

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

PREFACE.

IN completing the last volume of the condensed course of Mathematics, the author deems it proper to say a few words in explanation of the general plan of the series.

There is a growing belief among educators that our text-books contain a great deal of matter which is not essential, either to continuity or to completeness, and that they are to this extent overcrowded and unnecessarily voluminous. The desire for condensed, but not emasculated, books is well expressed by an eminent authority in educational matters who says: "Small text-books, containing only the essentials of the subjects treated of—only those parts that have life in them, parts that cannot be eliminated without leaving the subjects imperfect—are rare. * * * Such books we must have, if we use text-books at all." The demand for small and complete books comes from every department of instruction, but from none more emphatically, than from that of Mathematics. The present series is designed to meet this demand by furnishing a set of books, embracing within moderate limits every mathematical principle necessary to the fullest academic, or technical

education. Commencing with the simplest ideas of number, the successive volumes conduct the student by easy gradation through all the essential principles of Arithmetic, Algebra, Geometry, Trigonometry, Analytics, and the Calculus.

The entire course is treated as a unit, each part being adapted to all the others, and all the parts being so arranged as to form a symmetrical whole. No effort has been spared to make the definitions clear, and the illustrations full, and the treatment of the subject throughout has been intended to afford the best results with the least expenditure of time and labor—in a word, to make the series *concise* in demonstration, *consecutive* in arrangement, *complete* in detail.

MANUAL OF GEOMETRY.

INTRODUCTION.

FUNDAMENTAL CONCEPTIONS.

1. A portion of space, limited in all directions, is called a **volume**; that which separates a volume from the rest of space is called a **surface**. If two surfaces intersect, or cut each other, that which is common to both is called a **line**; if two lines intersect, that which is common to both is called a **point**.

General Definitions.

2. A **magnitude** is anything that can be measured, that is, whose value can be expressed in terms of some thing of the same kind, taken as a unit.

3. A **point** is that which has position, but no magnitude.

4. A **line** is that which has length, without breadth or thickness.

5. A **surface** is that which has length and breadth without thickness.

6. A **volume** is that which has length, breadth, and thickness.

Straight Lines and Curved Lines.

7. A **straight line** is a line whose direction does not change at any point; thus, AC is a straight line.

It is assumed that one straight line, and only one, can be drawn through any two points.

8. A broken line is a line made up of straight lines lying in different directions; thus, ACDE is a broken line.

9. A curved line, or a curve, is a line whose direction changes at every point; thus, ACD is a curved line.

When the term *line* is used by itself, a *straight line* is always meant.

Planes and Curved Surfaces.

10. A plane is a surface such that a straight line through any two of its points lies wholly in the surface.

11. A curved surface is a surface of which no part is plane.

Generation of Lines and Surfaces.

12. If a point moves through space in accordance with a fixed law it is said to generate, or trace out, a line; the moving point is called the *generatrix*, and the law that governs its motion is called the law of generation.

The law of generation determines the kind of lines generated.

13. If a line moves through space in accordance with a fixed law it is said to generate a surface; the moving line is the *generatrix*, and the law which governs its motion is the law of generation.

Angles.

14. An angle is the inclination of two lines that meet at a common point; the two lines are called *sides* and their common point is the *vertex*: thus, the inclination of OA and OC is an angle, whose sides are OA and OC, and whose vertex is O.

If an angle stands by itself it may be designated by a single letter placed at the vertex; if two angles have a common vertex each is designated by three letters, of which the middle one denotes the vertex and the others the two sides: thus, the angle between QP and QR is called the angle Q; that between OA and OC is called the angle AOC; and that between OC and OD is called the angle COD.

Definition and Division of the Subject.

15. Lines, surfaces, volumes, and angles are called geometrical magnitudes.

16. Geometry is that branch of mathematics which treats of the properties and relations of geometrical magnitudes.

17. Geometry is divided into two parts: geometry of two dimensions, or plane geometry, in which the magnitudes considered lie in the same plane; and geometry of three dimensions in which the magnitudes considered do not lie in the same plane.

All the magnitudes considered in the first five books are supposed to lie in the same plane.

Definitions of Terms.

18. A theorem is an assertion whose truth is to be proved; the reasoning employed in making the proof is called a demonstration.

A problem is a question proposed, requiring an answer; the operation of finding the answer is called a solution.

Both theorems and problems are called propositions.

19. An axiom is an assertion whose truth is universally admitted.

20. A postulate is a problem whose solution is taken for granted.

21. A lemma is a proposition introduced out of the

regular course to aid in the demonstration of a theorem, or in the solution of a problem.

22. A **corollary** is an obvious consequence of one or more propositions.

A **scholium** is an explanatory remark made with reference to one or more preceding propositions.

23. An **hypothesis** is a supposition made either in the enunciation of a proposition or in the course of a demonstration.

24. The following are some of the most important **axioms** and **postulates**.

Axioms.

1°. Things equal to the same thing are equal to each other.

2°. If equals are added to equals, the sums are equal.

3°. If equals are subtracted from equals, the remainders are equal.

4°. If equals are multiplied by equals, the products are equal.

5°. If equals are divided by equals, the quotients are equal.

6°. The whole is greater than any of its parts.

7°. The whole is equal to the sum of all its parts.

8°. A straight line is the shortest path between two points.

Postulates.

1°. A straight line can be drawn through any two points.

2°. A straight line can be prolonged to any extent.

3°. A straight line can be constructed equal to a given straight line.

4°. A straight line can be bisected, that is, divided into two equal parts.

5°. An angle can be constructed equal to a given angle.

6°. An angle can be bisected.

Notation.

25. The signs and methods of notation used in Algebra are also employed in Geometry. The principal signs are the ordinary signs of *addition*, $+$; of *subtraction*, $-$; of *multiplication*, \times ; of *division*, \div ; the *radical sign*, $\sqrt{}$; and the *signs of proportion*, $:$, $::$, $..$. The *vinculum* and the *parenthesis* are used to connect quantities that are to be operated on as a single quantity ; *coefficients* are used to denote multiples ; and *exponents* to denote powers. The symbols 1° , 2° , 3° , &c. are read *first*, *second*, *third*, &c. In addition to these methods of denotation, geometrical magnitudes are represented by pictorial symbols, called *geometrical figures*, in which points and lines are designated by letters placed so as to be convenient for reference.

NOTE.—In the references throughout this work, *P.* stands for proposition, *B.* for book, *Cor.* for corollary, *Ax.* for axiom, *Prob.* for problem, *Post.* for postulate, and *Scho.* for scholium. In referring to subjects in the same book the number of the book is not given.

BOOK I.

LINES, ANGLES, AND POLYGONS.

Generation and Classification of Angles.

26. An angle may be generated by a line revolving about one of its points in the same manner that one leg of a pair of compasses turns about the hinge. Thus, if we suppose OC to start from the position OA and to revolve about O in the direction indicated by the arrow, it will generate an angle AOC , whose magnitude will obviously depend on the amount of turning, and not at all on the length of OC .

In this explanation we only consider that part of the revolving line which lies on one side of the vertex; if we suppose the line to be prolonged through the vertex, the prolongation may be regarded as a second line lying in an opposite direction. Thus, if we suppose QC to start from the position PA and to revolve about O in the direction indicated by the arrows, the part OC will generate an angle AOC and the opposite part, OQ , will generate another angle POQ .

27. If a line DO meets a second line PA so as to form two angles, these angles are said to be adjacent. If the adjacent angles are equal, each is called a **right angle**, and the first line is said to be **perpendicular** to

the second. Thus, if $\angle DOA$ and $\angle DOP$ are equal, each is a right angle, and OD is perpendicular to PA , at O .

The point O is called the *foot* of the perpendicular OD .

28. An **acute angle** is one that is less than a right angle; an **obtuse angle** is one that is greater than a right angle: thus, $\angle AOC$ is *acute*, and $\angle COP$ is *obtuse*.

The angles $\angle AOC$ and $\angle COP$ are both called **oblique**, and the line OC is said to be *oblique* to PA .

29. If two lines **intersect**, that is, cross each other, they form four angles about the point of intersection. Those that

lie on the same side of one line and on opposite sides of the other are called **adjacent**, and those that lie on opposite sides of both are called **opposite**, or **vertical angles**:

thus, $\angle AOC$, $\angle COP$, are *adjacent*, and $\angle AOC$, $\angle POQ$, are *opposite* angles.

Any one of the four angles about O has two adjacent angles and one opposite angle.

PROPOSITION I. THEOREM.

If two lines intersect, the opposite angles which they form are equal.

Let PA and QC be two lines that intersect, and suppose PA to remain fixed whilst QC revolves about their common point, O . If we suppose the moving line to start from the position PA and to revolve in the direction indicated by the arrows till it comes into some other position, QC , the part OC will generate the angle $\angle AOC$ and the opposite part OQ will generate the opposite angle $\angle POQ$; but the amount

of turning of OC is obviously the same as that of OQ ; hence, $\angle AOC$ and $\angle POQ$ are equal. If we now suppose the motion to continue until OC falls on OP and OQ on OA , the former will generate the angle $\angle COP$ and the latter will generate the angle $\angle QOA$, and for the same reason as before these angles are equal. Hence, in every position of QC , we have, $\angle AOC$ equal to $\angle POQ$ and $\angle COP$ to $\angle QOA$, which was to be proved.

PROPOSITION II. THEOREM.

One perpendicular, and one only, can be drawn to a given line at a given point.

Let PA be the given line and O the given point. Suppose a line OC to start from the position OA and to revolve about O in the indicated direction. At the beginning of the motion, $\angle AOC$ is less than $\angle COP$; as the motion progresses $\angle AOC$ increases, $\angle COP$ decreases, and their difference continually diminishes, until the revolving line comes to some position, OD , in which the two angles are equal; after passing this position the first angle becomes greater than the second, and their difference continually increases till the revolving line comes to the position OP : there is therefore one position of the revolving line, and but one, in which the two angles are equal. Hence, there is one perpendicular to PA at O , and only one, which was to be proved.

Cor. 1. If OD is perpendicular to PA , its prolongation OQ is also perpendicular to PA . For, from P. 1, $\angle AOD$ is equal to

POQ , and DOP to QOA ; consequently POQ is equal to QOA , (Ax. 1°): hence, OQ is perpendicular to PA .

Cor. 2. If one of the four angles formed by two lines that intersect is a right angle, the other three are right angles and the two lines are mutually perpendicular to each other.

Scho. A right angle is an angle that may be generated by a line OC in revolving through a quarter of a complete revolution; hence, all right angles are equal.

PROPOSITION III. THEOREM.

The sum of the adjacent angles formed by one line meeting another is equal to two right angles.

Let PA be any line and let OC be another line meeting it at O . Suppose OC to start from the position OA , and to revolve about O in the indicated direction. As the angle AOC increases, its adjacent angle COP diminishes by an equal amount; hence, the sum of the two is always the same whatever may be the position of OC . But, when OC is perpendicular to PA , the sum of the two angles is equal to two right angles; it is therefore equal to two right angles for every position of OC , *which was to be proved.*

Cor. 1. If PA and QC intersect, the sum of any two of the adjacent angles which they form is equal to two right angles. For, from P. 1, AOC is equal to POQ , and COP to QOA ; hence, (Ax. 2°), the sum of POQ and QOA is equal to the sum of AOC

and COP, that is, to two right angles. In like manner it may be shown that the sum of QOA and AOC, and that the sum of COP and POQ is equal to two right angles.

Cor. 2. The sum of all the angles formed by any number of

lines meeting at any point of a given line, and lying on the same side of that line, is equal to two right angles.

For, the sum of the angles AOC, COE, EOF, and FOP, is obviously equal to the sum of AOC and COP, which is equal to two right angles.

Cor. 3. The sum of all the angles formed by any number of lines meeting at a common point is equal to four right

angles. For the sum of the angles AOC, COF, FOQ, QOS, and SOA is equal to the angular space generated by OA whilst turning through a complete revolution, that is, it is equal to four right angles, (P. 2, *Scho.*).

Definitions and Remarks.

30. Two angles are said to be **complementary** when their sum is equal to a right angle; they are said to be **supplementary** when their sum is equal to two right angles.

Complementary angles are always acute. Of two supplementary angles both may be right angles, or one may be acute and the other obtuse.

It follows from the preceding definitions, that complements of equal angles are equal, and that supplements of equal angles are equal.

PROPOSITION IV. THEOREM.

If the sum of two adjacent angles is equal to two right angles, their exterior sides are in the same straight line.

Let the sum of AOC and COP be equal to two right angles; then is COP the supplement of AOC , by the definition just given; but the angle that OC makes with the prolongation of AO is the supplement of AOC , by P. 3. Hence, the angle COP is identical with the angle that CO makes with the prolongation of AO ; consequently, the side OP must be identical with the prolongation of AO , *which was to be proved.*

Scho. Proposition IV is the **converse** of Proposition III, that is, the *hypothesis* and *conclusion* of the one are respectively the *conclusion* and *hypothesis* of the other.

PROPOSITION V. THEOREM.

Through a point without a line one perpendicular can be drawn to that line, and but one.

1°. Let PA be any line and D a point without the line. Suppose that part of the plane of the figure which lies above PA to revolve about PA (as a door turns on its hinges), till it falls on the part below PA , and let R be the revolved position of D ; then suppose the plane to revolve back to its primitive position and draw DR cutting PA at O . The line DR will be perpendicular to PA ; for, if we again suppose the upper part of the plane to revolve about PA till it falls on the lower part, the point D will fall at R , and because O remains fixed, the angle DOP will fall upon, and coincide with, POR ; consequently DOP is equal to POR ; but POR is equal to AOD , (P. 1.); POD is therefore equal to AOD , that is, DO is perpendicular to PA , *which was to be proved.*

2°. Furthermore, no other line can be drawn through D perpendicular to PA; for, if possible, let DQ be such a line,

and draw QR. It may be shown in the same manner as before that the angles DQP and PQR are equal, and since DQP is a right angle, by hypothesis, the sum of DQP and PQR is equal to two right angles, and consequently DQR is a straight line (P. 4.). But this is impossible, because only one straight line can be drawn

through two points; hence, the supposition that a second line can be drawn through D perpendicular to PA is false; DR is therefore the only line that can be drawn through D perpendicular to PA, *which was to be proved.*

Scho. The second part of the preceding demonstration is an example of the method of reasoning called the *reductio ad absurdum*. This method consists in assuming a proposition such that either it or the one to be demonstrated *must* be true, the other one being false; the assumed proposition is then shown to be false, from which it follows that the one to be demonstrated *must* be true.

Definitions.

31. A **polygon** is a portion of a plane bounded by straight lines; the bounding lines are called **sides**; the points in which the sides meet are called **vertices**; and the entire broken line that bounds the polygon is called the **perimeter**. Thus, ACDE is a polygon whose sides are AC, CD, DE, and EA; whose vertices are A, C, D, and E; and whose perimeter is the broken line ACDEA.

32. The side on which a polygon is supposed to stand is called its **base**; a line joining any two vertices which are not consecutive is

called a **diagonal**; thus, AC is the base of the polygon, ACDE and AD, CE, are diagonals.

33. If all the sides of a polygon are equal, it is said to be equilateral; if all the angles are equal, it is said to be equiangular.

34. Polygons are named either from the number of their sides, or from the number of their angles: a polygon of three sides, is called a **triangle**; one of four sides, a **quadrilateral**; one of five sides, a **pentagon**; one of six sides, a **hexagon**; one of seven sides, a **heptagon**; one of eight sides, an **octagon**; and so on.

Classification of Triangles.

35. Triangles may be classified either with respect to the relations among their sides, or with respect to the relations among their angles.

36. When classified with respect to sides there are two classes; *scalene*, and *isosceles triangles*.

A **scalene triangle** is one that has no two sides equal; as ACD.

An **isosceles triangle** is one that has two equal sides; as EFG.

An *equilateral triangle* is a particular case of an isosceles triangle; its three sides are all equal.

37. When classified with respect to angles, there are two classes; *right-angled* and *oblique triangles*.

A **right-angled triangle** is one that has one right angle; as ACD.

The side AD, opposite the right angle, is called the **hypotenuse**.

An **oblique triangle** is one whose angles are all oblique ; as, EFG, HKL.

If one angle is obtuse, the triangle is **obtuse-angled** ; if all the angles are acute, the triangle is **acute-angled**.

PROPOSITION VI. THEOREM.

The sum of any two sides of a triangle is greater than the third side.

Let ACD be any triangle.

The distance from A to D, measured on the broken line ACD, is greater than the distance measured on the straight line AD ; hence,

$$AC + CD > DA ; \dots\dots\dots (1)$$

which was to be proved.

Cor. The difference of any two sides of a triangle is less than the third side. For, if from both members of (1), we subtract either AC, or CD, say AC, we have

$$CD > DA - AC, \text{ or } DA - AC < CD.$$

Scho. In order that three lines may be sides of a triangle the sum of any two must be greater than the third, and the difference of any two must be less than the third.

PROPOSITION VII. THEOREM.

The sum of the lines drawn from a point within a triangle to the extremities of any side is less than the sum of the other two sides.

Let ACD be a triangle, and P a point within it. Draw PA and PC, and prolong AP to meet DC at Q. From P. 6, we have,

$$CP < CQ + QP ; \dots\dots\dots (1)$$

Adding PA to both members of (1), remembering that $QP + PA$ is equal to QA, we have,

$$CP + PA < CQ + QA \dots\dots\dots (2)$$

Again, we have,

$$QA < QD + DA; \dots\dots\dots (3)$$

Adding CQ to both members of (3), remembering that $CQ + QD$ is equal to CD, we have,

$$CQ + QA < CD + DA \dots\dots\dots (4)$$

Comparing (2) and (4), we have,

$$CP + PA < CD + DA,$$

which was to be proved.

PROPOSITION VIII. THEOREM.

If two sides and their included angle, in one triangle, are equal to two sides and their included angle, in another triangle, each to each, the triangles are equal in all their parts.

Let ACD and PQR be two triangles in which AC is equal to PQ, CD to QR, and ACD to PQR.

Let the triangle PQR be placed on ACD so that the angle Q shall coincide with C, QP falling on CA, and QR on CD; then, because R coincides with D, and P with A, RP coincides with DA, and consequently the triangles coincide throughout their whole extent; they are therefore equal in all their parts, *which was to be proved.*

Scho. 1. If PQR is situated in the manner indicated by the triangle on the right, it must be reversed, that is, turned completely over in its own plane, before it can be superposed on ACD.

Scho. 2. If two triangles are equal in all their parts, equal angles lie opposite the equal sides, and the reverse.

PROPOSITION IX. THEOREM.

If two sides of one triangle are equal to two sides of another triangle, each to each, and if the included angle in the first triangle is greater than the included angle in the second, the third side of the first is greater than the third side of the second, and conversely.

1st. Let ACD and PQR be two triangles in which AC is equal to PQ , CD to QR and $\angle ACD > \angle PQR$. From C draw CS equal to QR , and making $\angle ACS$ equal to $\angle PQR$; draw SA . The triangles PQR and ACS have AC equal to PQ , CS to QR and $\angle ACS$ to $\angle PQR$; they are therefore equal in all their parts, and consequently SA is equal to RP , (P. 8). In comparing SA with DA , there may be three cases: the vertex S may fall without the triangle ACD , it may fall within ACD , or it may fall on the side DA .

1°. If S falls without ADC ; from P. 6, we have,

$$DT + CT > CD, \dots\dots\dots (1)$$

and, $TA + TS > SA. \dots\dots\dots (2)$

adding (1) and (2), remembering that $DT + TA$ is equal to DA , and $CT + TS$ to CS , we have,

$$DA + CS > CD + SA; \dots\dots\dots (3)$$

subtracting CS from the first member of (3), and its equal CD from the second member, we have,

$$DA > SA, \text{ or } DA > RP,$$

which was to be proved.

2°. If S falls within ADC :
we have from P. 7,

$$CD + DA > CS + SA; \dots\dots\dots (1)$$

subtracting CD from the first member of (1), and its equal CS from the second member, we have,

$$DA > SA, \text{ or } DA > RP,$$

which was to be proved.

3°. If S falls on DA : we have, from Ax. 6°,

$$DA > SA, \text{ or } DA > RP,$$

which was to be proved.

Hence, the theorem is true in all cases.

2dly. *Conversely*, if DA is greater than RP , the angle ACD is greater than PQR . For, if ACD is less than PQR , DA is less than RP , from what has just been shown; if ACD is equal to PQR , DA is equal to RP from P. 8; hence, ACD is neither less than, nor equal to PQR ; it must therefore be greater than PQR , *which was to be proved.*

PROPOSITION X. THEOREM.

If two angles and their included side in one triangle are equal to two angles and their included side in another triangle, each to each, the triangles are equal in all their parts.

Let ACD and PQR be two triangles in which the angle A is equal to P , the angle C to Q , and the side AC to PQ .

Let the triangle PQR be placed on ACD , so that PQ shall coincide with its equal AC , the angle P with its equal A , and the angle Q with its equal C ; then will PR take the direction AD , QR the direction CD , and consequently R will fall on D ; the triangles, therefore, coincide throughout; hence, they are equal in all their parts, *which was to be proved.*

PROPOSITION XI. THEOREM.

If the sides of one triangle are equal to the sides of another triangle, each to each, the triangles are equal in all their parts.

Let ACD and PQR be two triangles in which AC is equal to PQ , CD to QR , and DA to RP .

The sides that include the angle A are equal to those that include the angle P , each to each; if therefore A is greater than P , CD is greater than QR , or if A is less than P , CD is less than QR , (P. 9); but CD is neither greater nor less than QR ; consequently A is neither greater nor less than P ; hence, A is equal to P . The two triangles have therefore two sides and their included angle in one, equal to two sides and their included angle in the other, each to each; hence, the triangles are equal in all their parts, (P. 8), *which was to be proved.*

PROPOSITION XII. THEOREM.

In an isosceles triangle the angles opposite the equal sides are equal.

Let ACD be an isosceles triangle in which CD is equal to DA . Let the base AC be bisected in E and from the vertex D draw DE .

The triangles AED and CED have the side AE equal to CE , the side DE common, and the side DA equal to DC ; they are therefore equal in all their parts, (P. 11). Hence, the angle A is equal to C , *which was to be proved.*

Cor. 1. An equilateral triangle is also equiangular.

Cor. 2. A line drawn from the *vertex* of an isosceles triangle to the middle of the *base* bisects the angle at the vertex, and is perpendicular to the base. For, from what has just been proved, the angle EDA is equal to EDC, and the angle DEA to DEC.

PROPOSITION XIII. THEOREM.

If two angles of a triangle are equal, their opposite sides are equal.

In the triangle ACD, let the angle A be equal to C.

If CD is not equal to DA, suppose DA to be the greater; on DA lay off AE equal to CD and draw CE. The triangles ACD and CAE, have the side AC common, the side CD equal to AE, by construction, and the angle ACD equal to EAC, by hypothesis; they are therefore equal in all their parts, (P. 8); but a part cannot be equal to the whole, (Ax. 6°); hence, the hypothesis that CD is not equal to DA is false; the two sides CD and DA are therefore equal, *which was to be proved.*

Cor. An equiangular triangle is equilateral.

PROPOSITION XIV. THEOREM.

If two angles of a triangle are unequal the sides opposite to them are unequal, and the greater side lies opposite the greater angle, and conversely.

1°. In the triangle ACD, let the angle A be greater than the angle C. Through A draw AQ making the angle QAC equal to ACQ; then is $AQ = CQ$, (P. 13). From the triangle AQD, we have, (P. 6), $AQ + QD > AD$, or substituting for AQ its equal CQ, re-

membering that $CQ + QD = CD$, we have, $CD > DA$, *which was to be proved.*

2°. *Conversely*, if CD is greater than DA , the angle A is greater than C . The angle A cannot be less than C , for in that case CD would be less than DA from what has just been shown ; the angle A cannot be equal to C because in that case we should have CD equal to DA , (P. 13) ; since A is neither less than C nor equal to C it must be greater than C , *which was to be proved.*

PROPOSITION XV. THEOREM.

If from a point without a line a perpendicular is drawn to that line and also oblique lines :

1°. *Any two oblique lines that meet the given line at equal distances from the foot of the perpendicular are equal ;*

2°. *Of two oblique lines that meet the given line at unequal distances from the foot of the perpendicular, that which meets it at the greater distance is the greater ;*

3°. *The perpendicular is less than any oblique line.*

Let D be a point lying without PA ; let DO be perpendicular to PA and let DP , DC , DA , be oblique lines, such that $OP = OC$, and $OA > OC$. Prolong DO , making OR equal to DO ; draw RC and RA .

1°. The triangles POD , DOC , have the side DO common, OP equal to OC by hypothesis, and the angles POD and DOC equal, because DO is perpendicular to PA ; they are therefore equal in all their parts, (P. 8) ; hence, DP is equal to DC , *which was to be proved.*

2°. Because AO is perpendicular to DR and OD equal to OR, we have, from what has just been shown, $DC = RC$, and $DA = RA$; but from P. 7, we have,

$$DA + RA > DC + RC;$$

substituting DA for its equal RA and DC for its equal RC, we have,

$$2DA > 2DC; \text{ or, } DA > DC,$$

which was to be proved.

3°. From P. 6, we have,

$$DO + OR < DC + CR;$$

substituting DO for its equal OR, and DC for its equal CR, we have,

$$2DO < 2DC; \text{ or } DO < DC,$$

which was to be proved.

Cor. 1. If DP is equal to DC, OP is equal to OC. For, if OP and OC were unequal, DP and DC would be unequal, from what has just been shown.

Cor. 2. Only two equal lines can be drawn from D to PA, and these lie on opposite sides of the perpendicular.

Cor. 3. If DA is greater than DC, OA is greater than OC. For if OA were equal to OC, DA would be equal to DC, and if OA were less than OC, DA would be less than DC, both of which conclusions are contrary to the hypothesis.

Cor. 4. In a right-angled triangle DOC, the hypotenuse DC is greater than either of the other sides, OC, OD; consequently the right angle O is greater than either of the other angles, that is, both the other angles are *acute*.

Cor. 5. The shortest line from D to PA is perpendicular to PA.

Scho. When the distance from a point to a line is spoken of, the *shortest* distance is always meant.

PROPOSITION XVI. THEOREM.

If one line is perpendicular to another at its middle point, any point of the first line is equally distant from the extremities of the second, and any point not on the first line is unequally distant from the extremities of the second.

1°. Let DR be perpendicular to PA at its middle point O, and let D be any point of the first line. Draw DP and DA. Then, because DR is perpendicular to PA, and because OP is equal to OA, we have DP equal to DA, (P. 15), *which was to be proved.*

2°. Let Q be any point not on DR. Draw QP cutting DR at D; also draw QA and DA. Then will DP be equal to DA from what has just been proved.

From P. 6, we have

$$QA < QD + DA;$$

Substituting DP for its equal DA, we have,

$$QA < QD + DP, \text{ or } QA < QP,$$

that is, QA and QP are unequal, *which was to be proved.*

Cor. 1. The line DR contains every point that is equally distant from P and A.

Cor. 2. If each point of a line is equally distant from the extremities of a second line, the first line is perpendicular to the second, at its middle point.

PROPOSITION XVII. THEOREM.

If two right-angled triangles have the hypotenuse and an acute angle of one, equal to the hypotenuse and an acute angle of the other, each to each, the triangles are equal in all their parts.

Let ACD and PQR be two triangles right-angled at C and Q , in which the hypotenuse AD is equal to PR and the angle A to P . Let PQR be placed on ACD so that the angle P shall coincide with A , PQ taking the direction AC and PR the direction AD ; then because PR is equal to AD , the vertex R will fall at D and RQ will coincide with the perpendicular from D to AC , that is, with the side DC (P. 5); hence, the vertex Q will fall at C , and the two triangles will coincide throughout their whole extent; they are therefore equal in all their parts, *which was to be proved*.

Definition.

38. The *bisectrix* of an angle is a line that divides it into two equal parts.

PROPOSITION XVIII. THEOREM.

Any point of the bisectrix of an angle is equally distant from the sides of that angle.

Let ACD be an angle whose bisectrix is CE , and let P be any point of CE . Draw PQ perpendicular to CA , and PR perpendicular to CD ; these will be the distances from P to the sides of the angle. The right-angled triangles CQP and CRP have a common hypotenuse CP , and the acute angle QCP in the first is equal to the acute angle RCP in the second; hence, they are equal in all their parts (P. 17), and consequently PQ is equal to PR , *which was to be proved*.

Definition.

39. Two lines lying in the same plane are *parallel*, when they cannot meet how far soever both may be prolonged.

If two lines are not parallel, they will meet if sufficiently prolonged.

PROPOSITION XIX. THEOREM.

If two lines are perpendicular to a third line, they are parallel to each other.

Let AC and DE be perpendicular to AD.

If AC and DE are not parallel, they will meet if prolonged, and from the point in which they meet we shall have two perpendiculars to the line AD, which is impossible (P. 5); hence, the lines cannot meet; they are therefore parallel, *which was to be proved.*

Cor. 1. A line can be drawn through any point, A, lying without DE, that will be parallel to DE. For, draw AD perpendicular to DE, and at A draw AC perpendicular to AD; then will AC be parallel to DE.

It is assumed that only one parallel to a given line can be drawn through a given point; hence, if a line is perpendicular to one of two parallels, it is also perpendicular to the other.

Cor. 2. If two lines AC and DE are parallel to a third, PQ, they are parallel to each other. For, let PA be perpendicular to PQ; it will also be perpendicular to both AC and DE; hence, AC and DE are parallel to each other.

Definitions.

40. A **secant** is a line that intersects or cuts another line. If two lines are cut by the same secant, the angles about the points of intersection, taken in pairs, receive different names according to their relative positions:

1°. Two angles that lie on the same side of the secant and between the other lines are called **interior angles on the same side**, as EQP, QPC;

2°. Two angles that lie on the same side of the secant and without the other lines are called **exterior angles on the same side**, as CPL, MQE;

3°. Two angles that lie on opposite sides of the secant and within the other lines, but not adjacent, are called **alternate interior angles**, as APQ, PQE;

4°. Two angles that lie on opposite sides of the secant, and without the other lines, but not adjacent, are called **alternate exterior angles**, as CPL, DQM;

5°. Two angles that lie on the same side of the secant, one without and one within the other lines, but not adjacent, are called **opposite exterior and interior angles**, as CPL, EQP.

PROPOSITION XX. THEOREM.

If two lines are cut by a secant, making the sum of the interior angles on the same side equal to two right angles, the two lines are parallel.

Let the lines AC and DE be cut by the secant LM, making the sum of the angles EQP and QPC equal to two right angles. Through O, the middle point of PQ, draw RS perpendicular to DE.

The angle RPO is the supplement of OPC, by P. 3, and the angle SQO is the supplement of OPC, by hypothesis; these angles are therefore equal; the angles POR and QOS are equal, because they are opposite angles (P. 1); and OP and OQ are equal, by hypothesis. Hence, the triangles OPR and OQS, have two angles and the included side in one equal to two angles and the included side in the other, each to

each, and are therefore equal; consequently, the angle ORP is equal to OSQ, that is, it is a right angle; the lines AC and DE are therefore perpendicular to RS; hence, they are parallel, *which was to be proved*.

Cor. From the relations among the angles about P and Q, we infer that AC and DE are parallel:

1°. If the sum of the exterior angles on the same side is equal to two right angles;

2°. If the alternate interior angles are equal;

3°. If the alternate exterior angles are equal;

4°. If the opposite exterior and interior angles are equal.

PROPOSITION XXI. THEOREM.

If two parallel lines are cut by any secant, the sum of the interior angles on the same side is equal to two right angles.

Let AC and DE be parallel, and let LM cut them at P and Q. Through O, the middle of PQ, draw RS perpendicular to DE; it will also be perpendicular to AC (P. 19, *Cor.* 1).

The right-angled triangles PRO and QSO have the hypotenuse OP equal to OQ, and the angles at O equal; the triangles are therefore equal in all their parts (P. 17), and consequently the angle RPO is equal to SQO. But the sum of RPO and OPC is equal to two right angles; hence, the sum of SQO and OPC is also equal to two right angles, *which was to be proved*.

Cor. 1. From the relations existing among the angles about P and Q, we infer that if AC and DE are parallel:

1°. The sum of the exterior angles on the same side is equal to two right angles;

- 2°. The alternate interior angles are equal ;
- 3°. The alternate exterior angles are equal ;
- 4°. The opposite exterior and interior angles are equal.

Cor. 2. If one of the interior angles on the same side is a right angle, the other one is also a right angle.

PROPOSITION XXII. THEOREM.

Two parallel lines are everywhere equally distant.

Let AC and DE be parallel ; from any two points of AC, as P and Q, draw PR and QS perpendicular to DE ; these lines will also be perpendicular to AC, and will therefore be the distances between AC and DE at those points. Draw the line QR. The right-angled triangles QPR and RSQ have the hypotenuse QR common and the acute angles PQR and SRQ equal (P. 21, *Cor. 1*) ; they are therefore equal in all their parts. Hence, PR and QS are equal, *which was to be proved.*

PROPOSITION XXIII. THEOREM.

If the corresponding sides of two angles are parallel and lie in the same, or in opposite directions, the two angles are equal.

1°. Let ACD and PQR be two angles in which CA is parallel to QP, and CD to QR, and let the corresponding sides lie in the same direction. Prolong AC till it meets QR at E.

Because EA and QP are parallel and are cut by QR, the angle PQR is equal to AER ; because QR and CD are parallel and are cut by EA, the angle AER is equal to ACD ; hence, PQR is equal to ACD, *which was to be proved.*

2°. Let ACD and PQR be two angles in which AC is parallel to PQ and CD to QR , and let the corresponding sides lie in opposite directions. Prolong CA in the opposite direction to E , and CD in the opposite direction to S . The sides of the angle ECS are then parallel to the sides of PQR and lie in the same direction; the angles are therefore equal. Now, PQR and ECS are equal from what has just been proved, and ECS and ACD are equal because they are opposite angles; hence, ACD and PQR are equal, *which was to be proved*.

Cor. 1. If two corresponding sides of two angles are parallel and lie in the same direction, and if the other sides are parallel and lie in opposite directions, the angles are supplementary. Thus, DCE and RQP are supplementary. For, DCE is the supplement of ACD and consequently of PQR .

Cor. 2. If the corresponding sides of two angles are perpendicular, each to each, the angles are either equal or supplementary. For, let SQP be perpendicular to CA and QR to CD . Then let the angle PQR be revolved about Q in the direction indicated by the arrows and through a quarter of a complete revolution. The line SQP will take the position $S'QP'$ parallel to CA , and QR will take the position QR' parallel to CD ; from what has been shown we have $P'QR'$, or its equal PQR , equal to ACD ; $R'QS'$, or its equal RQS , is the supplement of ACD . If the angles in question are both acute or both obtuse, they are equal; if one is acute and the other obtuse, they are supplementary.

Cor. 3. Two lines will intersect when sufficiently prolonged, if they are respectively perpendicular to two lines that intersect.

PROPOSITION XXIV. THEOREM.

The sum of the angles of any triangle is equal to two right angles.

Let ACD be any triangle. Prolong the side AC in the direction CE and draw CP parallel to AD .

Because CP is parallel to AD and AC cuts them, the angles ECP and CAD are equal (P. 21, *Cor. 1*); because CP is parallel to AD and CD cuts them, the angles PCD and CDA are equal. Hence, the sum of the angles of the triangle is equal to the sum of the angles ECP , PCD , and DCA ; but this sum is equal to two right angles, (P. 3, *Cor. 2.*); hence, the sum of the angles of the triangle is equal to two right angles, *which was to be proved.*

Cor. 1. The sum of any two angles of a triangle is equal to the supplement of the third angle, and conversely.

Cor. 2. Any exterior angle of a triangle, that is, the angle between the prolongation of any side and the side next in order, is equal to the sum of the opposite interior angles. Thus, $DCE = CDA + DAC$.

Cor. 3. The acute angles of a right-angled triangle are complementary.

Cor. 4. Each angle of an equiangular triangle is equal to one-third of two right angles, or to two-thirds of one right angle.

Definitions.

41. A salient polygon is a polygon such that no straight

line can cut its perimeter in more than two points; as, ACDE. All other polygons are called **re-entrant polygons**, as PQRST.

The polygons treated of in this work are supposed to be **salient**.

PROPOSITION XXV. THEOREM.

The sum of the angles of a polygon is equal to twice as many right angles as the polygon has sides, less four right angles.

Let ACDEG be a polygon and let O be a point within it. From O draw lines to each of the vertices of the polygon; these will divide the polygon into as many triangles as the polygon has sides.

The sum of the angles of each triangle is two right angles; hence, the sum of all the angles of all the triangles is equal to twice as many right angles as the polygon has sides. But, the sum of the angles of the polygon is equal to the sum of all the angles of all the triangles *diminished* by the sum of the angles about O; and the sum of all angles about O is equal to four right angles (P. 3, Cor. 3). Hence, the sum of the angles of the polygon is equal to twice as many right angles as the polygon has sides, *less four right angles, which was to be proved.*

Cor. The sum of the angles of a quadrilateral is equal to *four* right angles; the sum of the angles of a pentagon is equal to *six* right angles; the sum of the angles of a hexagon is equal to *eight* right angles; and so on.

Scho. Any angle of an equiangular polygon is equal to the sum of its angles divided by the number of its angles. Thus, any angle of an equiangular pentagon is equal to $\frac{1}{5}$ of 6 right angles, or to $\frac{2}{5}$ of a right angle.

Definitions.

42. A parallelogram is a quadrilateral whose opposite sides are parallel; as ACDE.

43. A rhombus is an equilateral parallelogram whose angles are oblique; as PQRS.

44. A rectangle is a parallelogram whose angles are right angles; as ACDE.

45. A square is an equilateral rectangle; as PQRS.

46. A trapezoid is a quadrilateral, two of whose sides are parallel and the other two not parallel; as ACDE.

The parallel sides are called respectively the *upper* and the *lower bases*. Thus, ED is the upper base and AC the lower base of the trapezoid ACDE.

PROPOSITION XXVI. THEOREM.

The opposite sides of a parallelogram are equal, each to each.

Let ACDE be a parallelogram, and let CE be one of its diagonals.

Because AC and ED are parallel and CE cuts them, the angle ACE is equal to DEC (P. 21, *Cor.*); and because AE and CD are parallel and CE cuts them, the angles CEA and ECD are equal. The triangles ACE and DEC have the side CE common, the angle ACE equal to DEC, and the angle CEA equal to DCE; they are therefore equal in all their parts (P. 10); hence, AC is equal to ED, and AE to CD, *which was to be proved.*

Cor. 1. Parallels included between parallels are equal.

Cor. 2. Either diagonal of a parallelogram divides the parallelogram into equal triangles.

Cor. 3. The opposite angles of a parallelogram are equal, each to each.

Cor. 4. If two parallelograms have two sides and their included angle in one, equal to two sides and their included angle in the other, each to each, they are equal.

PROPOSITION XXVII. THEOREM.

If the opposite sides of a quadrilateral are equal, each to each, the quadrilateral is a parallelogram.

Let ACDE be a quadrilateral in which AC is equal to ED and AE to CD. Draw CE.

The triangles ACE and DEC have the side CE common, AC equal to DE, and EA to CD; they are therefore equal in all their parts (P. 11); consequently, the angle ACE is equal to DEC, and CEA to ECD. Because the alternate interior angles ACE and DEC are equal, AC and ED are parallel (P. 20, *Cor.*), and because the alternate angles CEA and ECD are equal, AE and CD are parallel. The quadrilateral ACDE is therefore a parallelogram, *which was to be proved.*

PROPOSITION XXVIII. THEOREM.

If two sides of a quadrilateral are parallel and equal, the quadrilateral is a parallelogram.

Let ACDE be a quadrilateral in which AC and ED are parallel and equal. Draw CE.

Because AC and ED are parallel and CE

cuts them, the angle \widehat{ACE} is equal to \widehat{DEC} . The triangles ACE and DEC have the side CE common, the side AC equal to ED , and the included angle \widehat{ACE} equal to the included angle \widehat{DEC} ; they are therefore equal in all their parts (P. 8); consequently AE is equal to CD . Hence, the opposite sides of $ACDE$ are equal each to each, and the figure is a parallelogram (P. 27), *which was to be proved*.

Cor. If two points on the same side of a line are equally distant from that line, the line that joins them is parallel to the given line.

PROPOSITION XXIX. THEOREM.

The diagonals of a parallelogram mutually bisect each other.

Let $ACDE$ be a parallelogram whose diagonals intersect at O . The triangles ACO and DEO , have the side AC equal to DE , the angle \widehat{ACO} equal to \widehat{DEO} , and the angle \widehat{OAC} equal to \widehat{ODE} ; they are therefore equal in all their parts. Hence, OA is equal to OD , and OC to OE , *which was to be proved*.

Cor. The diagonals of a rhombus are perpendicular to each other. For, if CD is equal to DE , the triangle CDE is isosceles, and because DO is drawn from the vertex D to the middle of the base CE , the line DA is perpendicular to CE .

EXERCISES ON BOOK I.

Let the student demonstrate the following theorems:

1°. *If the sum of two adjacent angles is equal to two right angles, the bisectrices of these angles are perpendicular to each other.*

2°. *The bisectrices of two opposite angles of a parallelogram are parallel to each other.*

3°. *The bisectrices of two consecutive angles of a parallelogram are perpendicular to each other.*

4°. *If two triangles ACE and ACD , (Fig. of Art. 31), have the side AC common and the sides CE and AD intersecting each other, then will the sum of the sides CE and AD , which intersect, be greater than the sum of the sides AE and CD , which do not intersect.*

5°. *If two lines mutually bisect each other, their extremities are the vertices of a parallelogram.*

6°. *If the opposite angles of a quadrilateral are equal, each to each, the quadrilateral is a parallelogram.*

7°. *If the diagonals of a parallelogram are equal, the parallelogram is a rectangle.*

8°. *The diagonals of a rhombus are the bisectrices of the angles of the rhombus.*

9°. *If a line included between two parallels is bisected and if a second line is drawn through the point of bisection and limited by the parallels, then will the second line be bisected at the same point.*

BOOK II.

THE CIRCLE, AND THE MEASURE OF ANGLES.

Definitions.

47. A Circle is a portion of a plane bounded by a curve all of whose points are equally distant from a point within, called the **centre**. The bounding line is called the **circumference**.

The centre of a circle is also the centre of its circumference.

48. A **radius** is a line drawn from the centre to any point of the circumference, as **OA**.

All radii of the same circle, or of equal circles, are equal.

49. A **diameter** is a line drawn through the centre and limited by the circumference, as **AE**.

A diameter is double the radius; all diameters of the same circle, or of equal circles, are equal.

50. An **arc** is a part of a circumference, as **ACD**. The line that joins the extremities of an arc is called a **chord**; thus, **AD** is the chord of the arc **ACD** and also of the arc **AKD**.

A chord is said to **subtend** the arc to which it belongs; thus, **AD** subtends the arc **ACD** and also the arc **AKD**.

51. An angle at the centre is an angle formed by two radii, as AOD.

The intercepted arc ACD is said to subtend the angle AOD.

52. A sector is a part of a circle bounded by two radii and their intercepted arc, as AODC.

53. A segment is a part of a circle bounded by an arc and its chord, as ADC.

54. Similar arcs, similar sectors, and similar segments, are those which correspond to equal angles at the centre.

Two arcs cannot be made to coincide unless they belong to the same circumference, or to equal circumferences.

A circle, or a circumference, may be designated by two letters, one at the centre and the other at the extremity of any radius; thus, the circle whose centre is O and whose circumference is ACK is called the circle OA.

PROPOSITION I. THEOREM.

Any diameter divides the circle to which it belongs into two equal parts.

Let AE be any diameter of the circle OA: then are the parts ACE and AKE equal to each other.

Let the part of the plane above AE be revolved about that line till it falls on the part below; each point of the curve ACE will fall on some point of the curve AKE, because all the points of both are equally distant from O; hence, the two parts of the circle coincide throughout; they are therefore equal, *which was to be proved.*

Cor. Any diameter bisects a circumference.

Scho. The segments formed by a diameter are *semi-circles*, and the arcs subtended by a diameter are *semi-circumferences*.

PROPOSITION II. THEOREM.

A diameter is greater than any other chord.

Let AD be any chord, not a diameter, of the circle OA, and let AE be a diameter through A: then is AE greater than AD.

Draw the radius OD.

The sum of the radii OA and OD is greater than AD (P. 6, B. 1); but the sum of OA and OD is equal to AE; hence, AE is greater than AD, *which was to be proved*.

Scho. The segments ACD and AKD are unequal; the arcs ACD and AKD, subtended by AD, are also unequal.

PROPOSITION III. THEOREM.

Equal angles at the centres of equal circles are subtended by equal arcs; and conversely, equal arcs subtend equal angles at the centre.

1°. Let AOD and EQG be equal angles at the centres of the equal circles OA and QE: then are the arcs ACD and EFG equal.

Let the sector EQG be placed on the sector AOD so that the angle Q shall coincide with the angle O; the point E will fall on A and the point G on D, and since all the points of the arcs EFG and ACD are

equally distant from O, the two arcs will coincide throughout; they are therefore equal, *which was to be proved*.

2°. *Conversely*, if the arcs ACD and EFG are equal, the angles AOD and EQG are equal.

Let the sector EQG be placed on the sector AOD so that the arc EFG shall fall on ACD; the radius QE will fall on OA and the radius QG will fall on OD, and consequently the angles EQG and AOD coincide; they are therefore equal, *which was to be proved*.

Cor. 1. The radius that bisects an angle at the centre bisects the corresponding arc, and *conversely*, the radius that bisects an arc bisects the corresponding angle at the centre.

Cor. 2. If radii are drawn dividing an angle at the centre into any number of equal parts, they will divide the corresponding arc into the same number of equal parts, and *conversely*, the radii that divide an arc into any number of equal parts divide the corresponding angle at the centre into the same number of equal parts.

Cor. 3. Two diameters, perpendicular to each other, form four angles at the centre, each equal to a right angle; they also divide the circumference into four arcs each equal to a quadrant, that is, to a quarter of a circumference; hence, a right angle at the centre is subtended by a quadrant.

Scho. The preceding proposition holds good if the angles and arcs belong to the same circle.

PROPOSITION IV. THEOREM.

In equal circles, equal arcs are subtended by equal chords; and conversely, equal chords subtend equal arcs.

1°. In the equal circles OA and QE let the arcs ACD and EFG be equal: then are the chords AD and EG equal.

Draw the radii OA , OD , QE , and QG .

Because the arcs ACD and EFG are equal, the angles O and Q are equal (P. 3), and consequently the triangles AOD and EQG have two sides and their included angle equal, each to each; they

are therefore equal in all their parts (P. 8, B. 1); hence, AD and EG are equal, *which was to be proved*.

2°. *Conversely*, if the chords AD and EG are equal, the arcs ACD and EFG are equal.

The triangles AOD and EQG have their sides equal each to each; they are therefore equal in all their parts (P. 11, B. 1); the angle O is therefore equal to the angle Q , and consequently their subtending arcs ACD and EFG are equal, *which was to be proved*.

Scho. This proposition holds good when the arcs and their chords belong to the same circle.

PROPOSITION V. THEOREM.

The radius that is perpendicular to a chord bisects that chord.

Let AD be any chord in the circle OA , and let OC be perpendicular to it at H : then is AH equal to DH .

Draw the radii OA and OD .

The point O lies without the line AD , the oblique lines OA and OD are equal, being radii of the same circle, and OH is drawn perpendicular to AD ; hence, AH is equal to DH (P. 15, Cor. 1, B. 1), *which was to be proved*.

Cor. The radius OC bisects the angle AOD , and also the corresponding arc ACD .

Scho. The centre of a circle, the middle of any chord, and the middle of the subtended arc lie in a line perpendicular to the chord; hence, a line that passes through any two of these points will pass through the other one and be perpendicular to the chord, and a line that passes through any one of the points and is perpendicular to the chord will pass through the other two.

PROPOSITION VI. THEOREM.

In equal circles, equal chords are equally distant from the centres.

In the equal circles OA and QE , let the chords AD and EG be equal: then are they equally distant from O and Q .

Draw OH perpendicular to AD , and QK perpendicular to EG ; draw also the radii OA , OD , QE , and QG .

In the triangles ADO and EGQ , the side AD is equal to EG , DO to GQ , and OD to QE ; hence, the angle OAH is equal to QEK (P. 11, B. 1). In the right-angled triangles AHO and EKQ , the hypotenuse OA is equal to QE , and the angle OAH to QEK ; hence, OH is equal to QK (P. 16, B. 1). But OH is the distance of AD from O , and QK is the distance of EG from Q ; hence, their distances are equal, *which was to be proved.*

Scho. This proposition holds true when the chords belong to the same circle.

PROPOSITION VII. THEOREM.

Through three points, not in a straight line, one circumference may be made to pass, and but one.

1°. Let A , C , and D be three points, not in a straight line: then can one circumference be made to pass through them, and only one.

Draw AC and CD. Let FH be perpendicular to AC at its middle point, and let GK be perpendicular to CD at its middle point; these lines will intersect at some point, O (P. 23, *Cor.* 3, B. 1). Draw OA, OC, and OD.

Each point of FO is equally distant from A and C (P. 16, B. 1); hence, OA is equal to OC. In like manner it may be shown that OC is equal to OD. Hence, O is equally distant from A, C, and D; consequently, a circumference whose centre is O and whose radius is OA will pass through A, C, and D, *which was to be proved.*

2°. The line FO contains all the points that are equally distant from A and C, and GO contains all the points that are equally distant from C and D; hence, O is the only point that is equally distant from A, C, and D; the circumference just described is therefore the only one that can pass through these points, *which was to be proved.*

Cor. Two circumferences cannot intersect in more than two points; for if they could intersect in three points, two circumferences could pass through three points, which is impossible.

Definitions.

55. A **secant** is a line that cuts a circumference in two points, as DC. A **tangent** is a line that touches a circumference in one point and has no other point in common with it, as RPT. The point P, at which it touches the circumference, is called the **point of contact**, or the **point of tangency**.

The circumference OC is also said to be tangent to RPT.

56. If two circumferences intersect, the corresponding circles are called **secant circles**; if they have but one point in common they are **tangent** to each other at that point.

57. The line passing through the centres of two circles is called their **line of centres**. The distance between the centres of two circles is called their **central distance**.

PROPOSITION VIII. THEOREM.

The perpendicular to a radius at its extremity is tangent to the circumference at that point; and conversely, a tangent to a circumference is perpendicular to the radius drawn to the point of contact.

1°. Let TS be perpendicular to the radius OP at P; then is it tangent to the circumference OP at P.

Let Q be any point of TS, except P, and draw OQ.

Because OQ is oblique and OP perpendicular to TS, OQ is greater than OP (P. 15, B. 1), that is, Q lies without the circumference OP; hence, P is the only point of TS that lies on the circumference; TS is therefore tangent to the circumference at P, *which was to be proved*.

2°. *Conversely*, let TS be tangent to the circumference OP at P: then is TS perpendicular to OP at P.

Because TS is a tangent, all its points except P lie without the circumference; hence, OP is the shortest line that can be drawn from O to TS; it is therefore perpendicular to TS at P (P. 15, Cor. 5, B. 1), *which was to be proved*.

Cor. 1. Only one tangent can be drawn to a circumference at the same point.

Cor. 2. Tangents at the extremities of the same diameter are parallel; and conversely, if two tangents are parallel the line joining their points of contact is a diameter.

Cor. 3. Parallel tangents intercept equal arcs of a circumference, each being a semi-circumference.

PROPOSITION IX. THEOREM.

Parallel secants intercept equal arcs of a circumference.

Let PQ and RS be parallel secants: then are the arcs PR and QS equal.

Draw a radius OT perpendicular to RS; it will also be perpendicular to PQ.

Because OT is perpendicular to RS and PQ it bisects the arcs RTS and PTQ (P. 5, *Cor.*); hence, the difference between the arcs TR and TP is equal to the difference between TS and TQ, that is, PR and QS are equal, *which was to be proved.*

Cor. The arcs intercepted by a secant and a parallel tangent are equal. For if the tangent GH is parallel to PQ the perpendicular radius OT passes through the point of contact, T, and consequently QT and PT are equal.

PROPOSITION X. THEOREM.

The line of centres of two secant circles is perpendicular to their common chord at its middle point.

Let the circumferences OA and QA intersect at A and C, and let AC be their common chord: then is the line of centres LM perpendicular to AC at its middle point.

Because A and C are on the circumference OA they are

equally distant from O, and because they are on the circumference QA they are equally distant from Q; hence, LM has two of its points equally distant from A and C, it is therefore perpendicular to AC at its middle point (P. 16, Cor. 2, B. 1), *which was to be proved.*

Cor. If two circumferences are tangent to each other their point of contact is on their line of centres. For if the circumference whose centre is Q is moved either to the right or left, its centre remaining on LM, the points of intersection will always be equally distant from the line of centres, and if the motion is sufficiently continued these points will meet on the line of centres, and the two circumferences will be tangent to each other at that point.

If the circumference is moved towards M the circumferences become tangent externally; if moved towards L they become tangent internally.

PROPOSITION XI. THEOREM.

If two circumferences intersect, their central distance is less than the sum, and greater than the difference of their radii.

Let the circumferences OC and QC intersect, and let OC and QC be radii drawn to one of the points of intersection.

In the triangle OQC the side OQ is less than the sum, and greater than the difference, of QC and OC (P. 6, B. 1), *which was to be proved.*

PROPOSITION XII. THEOREM.

If two circles are tangent externally, their central distance is equal to the sum of their radii; if tangent internally their central distance is equal to the difference of their radii.

1°. If the circumferences are tangent externally at E, it is obvious that OQ is equal to the sum of OE and QE, which was to be proved.

2°. If the circumferences are tangent internally at E, it is obvious that OQ is equal to the difference of OE and QE, which was to be proved.

PROPOSITION XIII. THEOREM.

If one circumference lies wholly without another, their central distance is greater than the sum of their radii; if one circumference lies wholly within another, their central distance is less than the difference of their radii.

1°. Let the circumference QC lie wholly without the circumference OA, and let the line of centres cut the two circumferences at C and A.

It is obvious that OQ is greater than the sum of OA, and QC, which was to be proved.

2°. Let the circumference QC lie wholly within the circumference OA, and let the line of centres cut the circumferences at C and A. It is obvious that OQ is less than the difference of OA and QC, which was to be proved.

From this and the two preceding propositions we deduce

the following conclusions relating to the positions of two circles:

Cor. 1. If the central distance of two circles is greater than the sum of their radii, one circle lies wholly without the other.

Cor. 2. If the central distance is equal to the sum of their radii, the circumferences are tangent externally.

Cor. 3. If the central distance is less than the sum and greater than the difference of their radii, the circumferences intersect in two points.

Cor. 4. If the central distance is equal to the difference of their radii, the circumferences are tangent internally.

Cor. 5. If the central distance is less than the difference of their radii, one circumference is wholly within the other.

Two circles that have a common centre are said to be concentric.

Measure of angles.

58. To measure a thing is to find its *numerical* value in terms of something of the same kind taken as a *unit*. The *primary* unit of angular measure is the *right angle*. The right angle is divided into 90 equal parts called **degrees**; the degree is divided into 60 equal parts called **minutes**; the minute is divided into 60 equal parts called **seconds**. Seconds are divided into **tenths**, tenths into **hundredths**, and so on indefinitely. A right angle at the centre of a circle is subtended by a quadrant, and the radii that divide the right angle into equal parts also divide the quadrant into the same number of equal parts (P. 3, *Cor. 2*); these parts of the arc are called by the *same names* as the corresponding parts of the angle. Hence, the *numerical value* of an arc is the same as the numerical value of the angle which it subtends, that is, the arc contains the same number of degrees and parts of

a degree as the angle. We may therefore take the *numerical value* of an arc as the *numerical value* of the corresponding angle. In this sense, and in this sense only, we say that *an angle at the centre is measured by the intercepted arc*.

Because units of arc are definite portions of the circumferences to which they belong, the measure of an arc is independent of the length of its radius, in the same manner that the measure of an angle is independent of the length of its sides.

Degrees, minutes, and seconds are denoted by the symbols $^{\circ}$, $'$, $''$; thus, the expression $22^{\circ}, 25', 31''.34$ is read *22 degrees, 25 minutes, 31.34 seconds*.

Definitions.

59. An inscribed angle is an angle whose vertex is on the circumference and whose sides are chords; as ACD.

60. A polygon is said to be inscribed in a circle when all its sides are chords of the circumference; as ACDE.

61. A polygon is said to be circumscribed about a circumference when all its sides are tangent to the circumference; as PQRS.

62. A circle is circumscribed about a polygon when the circumference of the circle passes through all the vertices of the polygon.

63. A circle is inscribed in a polygon when the circumference of the circle is tangent to all the sides of the polygon.

PROPOSITION XIV. THEOREM.

An inscribed angle is measured by half of the intercepted arc.

There may be three cases: the centre of the circle may lie on one of the sides of the angle; it may lie within the angle; or, it may lie without the angle.

1°. Let the centre O lie on the side AC of the inscribed angle ACD .

Draw the radius OD .

The angle AOD is an exterior angle of the triangle OCD and is therefore equal to the sum of the opposite interior angles OCD and ODC , (P. 24, Cor. 2, B. 1); but OCD and ODC are equal, because they lie opposite the equal sides OD and OC (P. 12, B. 1); hence, ACD is half the angle AOD ; but AOD is an angle at the centre, and consequently is measured by the arc AD ; hence, the angle ACD is measured by half the arc AD , *which was to be proved*.

2°. Let the centre O lie within the inscribed angle ACD .

Draw the diameter CE .

From what has just been proved the angle ACE is measured by half the arc AE , and ECD by half the arc ED ; hence, the angle ACD is measured by half the sum of the arcs AE and ED , that is, by half the arc AD , *which was to be proved*.

3°. Let the centre O lie without the inscribed angle ACD .

Draw the diameter CE .

From what precedes, the angle ECD is measured by half the arc ED , and ECA by half the arc EA ; hence, ACD is measured

by half the difference of ED and EA , that is, by half the arc AD , *which was to be proved*.

Cor. 1. Angles, as ACD , AED , inscribed in the same segment ACD are equal, for each is measured by half the arc AD .

Cor. 2. An angle ACD inscribed in a semicircle is a right angle; for it is measured by half of a semicircumference, that is, by a quadrant.

Cor. 3. An angle ACD inscribed in a segment greater than a semicircle is acute, and an angle AFD inscribed in a segment less than a semicircle is obtuse: for the former is measured by an arc less than a quadrant and the latter by an arc greater than a quadrant.

Cor. 4. The angle between a tangent and a chord through the point of contact is measured by half the intercepted arc. For, let CT be tangent to the circumference OC at C , and let CA be a chord. Then draw any secant CH through C cutting the circumference at D . The angle ACH is measured by half the arc AD , whatever may be the position of CH . Now let CH be revolved about C in the indicated direction; the point D will approach C , and the arc AD will become more nearly equal to the arc AC ; finally when CH coincides with CT the point D coincides with C and the arc AD with the arc AC ; hence, the angle ACT is measured by half the arc AC .

PROPOSITION XV. THEOREM.

If two secants intersect within a circumference their included angle is measured by half the sum of the intercepted arcs; if they intersect without the circumference their included angle is measured by half the difference of the intercepted arcs.

1°. Let the secants AD and EF intersect at a point I within the circumference OA, and let DG be drawn parallel to EF.

The angle AIF is equal to ADG, because they are opposite exterior and interior angles (P. 21, *Cor.*, B. I); but ADG, and consequently AIF is measured by half the arc AFG, that is, by half the sum of the arcs AF and FG (P. 14); but the arc FG is equal to DE (P. 9); hence, the angle AIF is measured by half the sum of the arcs AF and DE, *which was to be proved.*

2°. Let the secants AD and EF intersect at a point I without the circumference OA, and let DG be drawn parallel to EF.

The angle I is equal to ADG because they are opposite exterior and interior angles; the angle ADG, and consequently the angle I is measured by half the arc AG, that is, by half the difference of the arcs AF and FG; but FG is equal to DE because they lie between the parallels DG and EF; hence, the angle I is measured by half the difference of the arcs AF and DE, *which was to be proved.*

EXERCISES ON BOOK II.

Let the student demonstrate the following theorems:

1°. *A straight line cannot cut a circumference in more than two points.*

2°. *In equal circles, the greater of two chords subtends the greater arc, and conversely.*

3°. *In equal circles, the less of two chords is at a greater distance from the centre.*

4°. *The angle between two tangents that intersect is measured by half the difference of the intercepted arcs.*

5°. *The sum of two opposite angles of an inscribed quadrilateral is equal to two right angles.*

6°. *An inscribed parallelogram is a rectangle.*

7°. *An inscribed quadrilateral formed by joining the extremities of two perpendicular diameters is a square.*

8°. *If circumferences are constructed on the equal sides of an isosceles triangle as diameters, they will intersect at the middle of the base.*

9°. *If two intersecting chords make equal angles with the diameter through their common point, they are equal.*

APPLICATION OF PRECEDING PRINCIPLES
TO THE SOLUTION OF PROBLEMS.

64. The problems treated of in Elementary Geometry are those whose elements are the straight line and the circle, and the only instruments actually required for their solution are the ruler, and the compasses or dividers. The ruler is used

to guide a pencil, or pen, in drawing a straight line, and the dividers are used for guiding a pencil or pen in drawing a circle. The student will find it convenient to have a *scale of equal parts*, a *triangular ruler*, and a *semicircular protractor*. It is assumed that the pupil understands the methods of drawing a straight line through two points, of laying off a line equal to a given line, and of drawing a circumference from a given centre with a given radius.

PROBLEM I.

To bisect a given line by a perpendicular.

Let AD be the given line. From A and D as centres, and with a radius greater than half of AD, draw two arcs intersecting at O and Q; then draw the line OQ, cutting AD at P. The line OQ is perpendicular to AD at its middle point P, because two of its points, O and Q, are each equally distant from A and D (P. 16, *Cor.* 2, B. 1).

PROBLEM II.

To erect a perpendicular to a line at a given point.

1°. Let P be any point of the given line. Assume a point A, at a convenient distance from P, and lay off PD equal to PA; then bisect AD by the line OQ, as in Prob. I, and OQ will be the required perpendicular.

2°. Let P be near one extremity of the line MN. Take a point O so that

OP shall make an acute angle with NM; with O as a centre and OP as a radius draw an arc meeting MN at A and the prolongation of AO at D; then draw PD and it will be the required perpendicular. For, the angle APD is inscribed in a semicircle and is consequently a right angle (P. 14, Cor. 2).

PROBLEM III.

To draw a perpendicular to a given line from a point without.

Let P be a point lying without the line MN. From P as a centre, with a radius greater than the shortest distance from P to MN, draw an arc cutting MN at A and D; from A and D as centres, with equal radii, draw two arcs intersecting at Q, and join P and Q. The line PQ having two of its points each equally distant from A and D, is perpendicular to MN (P. 16, Cor. 2, B. 1).

PROBLEM IV.

To draw a line through a given point parallel to a given line.

1°. Let P be the given point and MN the given line. From P as a centre, with a radius greater than the shortest distance from P to MN, draw an indefinite arc AL, and from A as a centre with the same radius draw the arc PD; draw also the chord of PD; then from A as a centre, with a radius equal to DP, draw an arc intersect-

ing AL at Q, and draw PQ; this will be parallel to MN. For, the arcs AQ and PD are equal, because they are arcs of equal circles subtended by equal chords (P. 4); the angles QPA and PAD are therefore equal (P. 3); hence, PQ is parallel to MN (P. 20, *Cor.*, B. 1).

2°. The problem may be solved by means of the triangular ruler as follows:

Let KL be an ordinary ruler and ACD a triangular ruler, right-angled at C. Place the edge DA of the triangular ruler so as to coincide with MN, and press the ruler KL against it so as to touch the edge CD; then

hold the ruler KL fast and move the triangular ruler along it till the edge passes through P; the line SP is parallel to MN, for the angles QSR and ADC are equal (P. 20, *Cor.*, B. 1).

PROBLEM V.

To construct an angle at a given point equal to a given angle.

Let ACD be the given angle, and OP be an indefinite line through the given point O. With C as a centre, and with

any convenient radius, CA, draw the arc AD, also draw its chord; then from O as a centre, with the same radius, draw the indefinite arc PL; from P as a centre, with AD as a radius, draw an arc cutting PL at Q; draw OQ and also the chord PQ. Then is the angle POQ equal to the angle ACD; for, the arcs PQ and AD are equal (P. 4), and consequently the corresponding angles are equal (P. 3).

PROBLEM VI.

To bisect a given angle.

Let ACD be the given angle. From C as a centre, with any radius, CA , draw the arc AD ; also draw the chord AD ; then bisect the chord AD by the perpendicular EP (Prob. 1); EP will pass through C and will bisect the angle ACD (P. 12, Cor. 2, B. 1).

PROBLEM VII.

To find the third angle of a triangle when the other angles are known.

Let A , and C , be two angles of a triangle. At any point, O , of the indefinite line MN , construct the angle NOL equal to A , and MOP equal to C ; then will POL be the required angle. For POL is the supplement of the sum of the angles NOL and MOP (P. 3, Cor. 2, B. 1), and consequently it is the supplement of the sum of the angles A and C ; it is therefore the required angle (P. 24, Cor. 1, B. 1).

PROBLEM VIII.

To construct a triangle when its sides are given.

Let A , C , and D be the given sides. On an indefinite line lay off PQ equal to A ; from P and Q as centres, with radii equal to C , and D , draw two arcs intersecting at R ; then draw QR and PR , the triangle PQR is the required triangle.

PROBLEM IX.

To construct a triangle when two sides and their included angle are given.

Let A , and C , be the given sides and D , the given angle. At any point, O , construct the angle POR equal to D , on one side lay off OP equal to A and on the other side lay off OR equal to C , and draw RP ; the triangle OPR , is the required triangle.

PROBLEM X.

To construct a triangle when two angles and their included side are given.

Let A , and C , be the given angles and let D be their included side. On an indefinite line lay off PQ equal to D ; at P and Q construct angles respectively equal to A and C and prolong their sides till they meet at R ; the triangle PQR is the required triangle.

PROBLEM XI.

To construct a triangle when two sides and the angle opposite one are given.

Let A and C be the given sides and let D be the angle opposite C .

Draw the indefinite line PM and at P construct an angle equal to D ; on PN lay off PQ equal to A ; from Q as a centre with a radius equal C , draw an arc cutting PM at R and R' ; then join R and Q and also R' and Q .

There may be several cases:

1°. The angle D may be acute and the side C may be less than the side A ; in this case denote the perpendicular distance from Q to PM by S . Then if C is greater than S , there will be two solutions as in the figure; if C is equal to S , there will be but one solution; if C is less than S , there will be no solution, that is, the problem is impossible.

2°. The angle D may be acute and C may be greater than A ; in this case one point of intersection will fall on one side of P and one on the other side of P , that is, on the prolongation of MP , and there will, therefore, be but one solution.

3°. The angle D may be a right angle, or an obtuse angle; in this case if C is greater than A there will be one solution, but if C is equal to, or less than, A , there will be no solution.

PROBLEM XII.

To draw a tangent to a circumference at a given point.

Let P be any point of the circumference OP , and let OP be the radius through that point. Draw ST perpendicular to OP at P ; then will ST be the required tangent (P. 8).

PROBLEM XIII.

To draw a tangent to a circumference and parallel to a given line.

Let AD be the given line, and let the circumference OP , be the given circumference. Draw the diameter PP' perpendicular to AD , and at the points in which

this meets the circumference draw ST and $S'T'$ perpendicular to PP' ; these will be parallel to AD (P. 19, B. 1) and tangent to the circumference OP (P. 8).

There are two solutions.

PROBLEM XIV.

To draw a tangent to a given circumference from a point without the circumference.

Let P be a point without the circumference OM . Draw PO , and on it, as a diameter, construct a circumference cutting the given circumference at M and N ; then draw PM and PN ; they will pass through P and be tangent to the circumference OM .

For draw the radii OM and ON ; the angles PMO and PNO are right angles because they are inscribed in semicircles; hence, PM and PN are perpendicular to the radii OM , and ON , at M , and N ; they are therefore tangent to the circumference OM ; the problem has *two* solutions.

Cor. The right-angled triangles PNO and PMO have a common hypotenuse PO , and the angles OPN , and OPM are equal, because they are measured by halves of equal arcs ON and OM ; the triangles are therefore equal in all their parts (P. 17, B. 1); hence, the tangents PN and PM are equal, and the line PO bisects the angle between them, also the angle NOM , between the radii to the point of contact.

PROBLEM XV.

To inscribe a circle in a given triangle.

Let ACD be the given triangle. Bisect the angles A and C , and prolong their bisectrices till they meet at O . The point

O is equally distant from the three sides of the triangle. For draw OM, ON, and OP, respectively perpendicular to AC, CD, and DA; because AO is the bisectrix of the angle A, OM and OP are equal, and because CO is the bisectrix of the angle C, OM and ON are equal (P. 18, B. 1); hence, the three perpendiculars are all equal. From O as a centre, with OM as a radius, describe a circumference and it will be tangent to all the sides of the given triangle; hence, the circle OM is inscribed in the triangle ACD.

PROBLEM XVI.

To circumscribe a circle about a given triangle.

Let ACD be the given triangle. Bisect AC and AD by perpendiculars (Prob. 1), and prolong them till they meet at O; from O as a centre with the radius OA describe a circumference and it will pass through all the vertices of the given triangle (P. 7); hence, the circle OA is circumscribed about the given triangle.

PROBLEM XVII.

To construct a segment on a given line that shall contain a given angle.

Let AC be the given line and Q the given angle. At A construct the angle CAT equal to Q, and draw AM perpendicular to AT at A; bisect AC by a perpendicular and prolong it till it meets AM at O; with O

as a centre and OA as a radius, draw a circumference; it will pass through C and be tangent to AT at A . Then will any angle, as ADC , inscribed in the segment CDA be equal to Q ; for the angles CDA and CAT are each measured by half the arc AC (P. 14, and P. 14, *Cor.* 4); but the angle CAT is equal to Q ; hence, CDA is also equal to Q .

ADDITIONAL PROBLEMS.

Let the pupil solve the following additional problems, using the annexed diagrams as guides to their solution.

PROB. XVIII. *Draw a line tangent to two given circumferences AP and BQ .*

PROB. XIX. *Through a given point P draw a circumference tangent to a given line CB at a given point B .*

PROB. XX. *Draw a circumference tangent to a given circumference CD and to a given line BP at a given point P .*

PROB. XXI. *Draw a circumference tangent to a given line TP and to a given circumference CQ at a given point Q.*

PROB. XXII. *Draw a circumference with a given radius tangent to a given line DP and to a given circumference CT.*

PROB. XXIII. *From two given points A and C draw two lines meeting on a given line BD and equal to each other.*

PROB. XXIV. *Inscribe a circle in a given quadrant BCDP.*

NOTE.—The figures in the margin are intended to suggest the methods of solution.

BOOK III.

RATIOS, PROPORTIONS, AND COMPARISON OF LINES.

Definitions and Principles.

65. The **ratio** of one magnitude to another of the same kind is the quotient of the *second* by the *first*. The first magnitude is called the **antecedent** and the second is called the **consequent**.

The operation of dividing one magnitude by another consists in dividing the *number of times* that any assumed unit is contained in the former by the number of times it is contained in the latter. If the magnitudes are commensurable the ratio is *exact*; if not, it is only *approximate*.

Let P and Q be two incommensurable magnitudes of the same kind. Suppose P to be divided into m equal parts, m being any whole number, and let Q contain n of these parts with a remainder less than one of them; then will,

$$\frac{Q}{P} = \frac{n}{m} \text{ to within less than } \frac{1}{m}.$$

The greater the value of m , the more nearly will $\frac{n}{m}$ approach to the true value of the ratio of P to Q.

66. The **limit** of a varying magnitude, is a value *towards* which that magnitude may approach, *with* which it may coincide, but *beyond* which it cannot pass.

It is assumed that whatever is true of all values of a varying magnitude is true of its limit.

67. Two quantities that differ by less than any assignable quantity are said to be equal to each other.

PROPOSITION I. THEOREM.

If the ratio of one magnitude to another of the same kind is equal to $\frac{n}{m}$, to within less than $\frac{1}{m}$, for all values of m , the true value of the ratio is the limit of $\frac{n}{m}$.

Let $\frac{Q}{P} = \frac{n}{m}$, to within less than $\frac{1}{m}$, for all values of m .

As m increases, $\frac{1}{m}$ diminishes and the value of $\frac{n}{m}$ becomes more nearly equal to $\frac{Q}{P}$; when m becomes greater than any assignable number, or *infinite*, $\frac{1}{m}$ becomes less than any assignable number or *zero*. Hence the true value of $\frac{Q}{P}$ is the limiting value of $\frac{n}{m}$, which was to be proved.

Cor. If each of the two ratios, $\frac{Q}{P}$ and $\frac{S}{R}$, is equal to $\frac{n}{m}$, to within less than $\frac{1}{m}$, for all values of m , the two ratios are equal; for, each is equal to the limiting value of $\frac{n}{m}$.

Additional Definitions and Principles.

68. A proportion is an expression of equality between two ratios.

A proportion may be written in either of two ways. Thus, if the ratio of a to b is equal to the ratio of c to d , the equality may be indicated by either of the following expressions: $\frac{b}{a} = \frac{d}{c}$, or $a : b :: c : d$; . . (1) either of these expressions may be read *a is to b as c is to d*.

The first and third terms of a proportion are **antecedents**; the second and fourth terms are **consequents**; thus in (1) a and c are antecedents, b and d are consequents.

The first and fourth terms are **extremes**; the second and third terms are **means**; thus, a and d are extremes, b and c are means.

The first ratio is called the **first couplet**; the second ratio is called the **second couplet**; thus, $a : b$ is the first, $c : d$, the second couplet.

The fourth term is said to be a **fourth proportional** to the other three; thus, d is a fourth proportional to a , b , and c .

If the second term is equal to the third term, either is a **mean proportional** between the other two; in this case, there are but three different terms, and the last is a **third proportional** to the other two; thus in the proportion

$$a : b :: b : c,$$

b is a mean proportional between a and c , and c is a third proportional to a and b .

69. Two varying quantities are **reciprocally proportional** when their product is equal to a fixed quantity; thus, if $xy = m$, x and y are reciprocally proportional.

70. **Equimultiples** of two quantities are the results obtained by multiplying both by the same quantity; thus, ma and mb are equimultiples of a and b , no matter what may be the value of m .

71. A **continued proportion** is an expression of continued equality among several ratios; thus,

$$a : b :: c : d :: e : f,$$

is a continued proportion. It is read, a is to b , as c is to d , as e is to f . This proportion may also be written,

$$a : c : e :: b : d : f,$$

in which case it is to be read as before.

Transformations.

72. If antecedents are made consequents and consequents antecedents, a proportion is said to be transformed by **inversion**.

73. If antecedent is compared with antecedent and consequent with consequent, the proportion is said to be transformed by **alternation**.

74. If the sum of antecedent and consequent, in each couplet, is compared with the corresponding antecedent, or with the corresponding consequent, the proportion is said to be transformed by **composition**.

75. If the difference of antecedent and consequent, in each couplet, is compared with the corresponding antecedent, or with the corresponding consequent, the proportion is said to be transformed by **division**.

PROPOSITION II. THEOREM.

If four quantities are in proportion, the product of the means is equal to the product of the extremes.

Assume the proportion,

$$a : b :: c : d, \text{ whence } \frac{b}{a} = \frac{d}{c}; \quad . . . \quad (1)$$

Multiplying both members of (1) by ac , and reducing, we have

$$bc = ad, \quad (2)$$

which was to be proved.

Cor. If $b = c$, there are but three different terms in the proportion, and we then have the square of the mean equal to the product of the extremes.

PROPOSITION III. THEOREM.

If the product of two quantities is equal to the product of two other quantities, the first two may be made the means and the other two the extremes of a proportion.

Assume the equation,

$$bc = ad, \quad (1)$$

dividing both members of (1) by ac , and reducing, we have,

$$\frac{b}{a} = \frac{d}{c}, \text{ or, } a : b :: c : d, \quad (2)$$

which was to be proved.

Cor. 1. Proportion (2) may be transformed in any way that will satisfy equation (1); we may therefore write the following proportions:

$$b : a :: d : c, \text{ and } a : c :: b : d;$$

hence, if four quantities are in proportion, they are also in proportion *by inversion*, and *by alternation*.

Cor. 2. If a is greater than b , c must be greater than d ; if a is equal to b , c must be equal to d ; if a is less than b , c must be less than d .

PROPOSITION IV. THEOREM.

If a couplet in each of two proportions is the same, the remaining couplets will form a proportion.

Assume the proportions,

$$a : b :: c : d, \text{ whence } \frac{b}{a} = \frac{d}{c}, \quad . . . \quad (1)$$

and $a : b :: e : f, \text{ whence } \frac{b}{a} = \frac{f}{e}; \quad . . . \quad (2)$

placing the second members of (1) and (2) equal, we have,

$$\frac{d}{c} = \frac{f}{e}, \text{ or } c : d :: e : f, \quad \quad (3)$$

which was to be proved.

Cor. If the antecedents of two proportions are equal, each to each, the corresponding consequents will form a proportion; for, if we have,

$$a : c :: b : d, \text{ and } a : e :: b : f,$$

we have by alternation,

$$a : b :: c : d, \text{ and } a : b :: e : f,$$

and consequently,

$$c : d :: e : f.$$

PROPOSITION V. THEOREM.

If four quantities are in proportion, they are in proportion by composition.

Assume the proportion,

$$a : b :: c : d, \text{ whence } \frac{b}{a} = \frac{d}{c}; \quad . . . \quad (1)$$

adding each member of the preceding equation to 1, we have

$$1 + \frac{b}{a} = 1 + \frac{d}{c}, \quad \text{or} \quad \frac{a+b}{a} = \frac{c+d}{c}; \quad . \quad . \quad (2)$$

whence the proportion,

$$a : a + b :: c : c + d. \quad . \quad . \quad . \quad (3)$$

From (1) and (3) we have (P. 4, Cor.),

$$b : a + b :: d : c + d. \quad . \quad . \quad . \quad (4)$$

From (3) and (4) we have, by inversion,

$$a + b : a :: c + d : c, \quad \text{and} \quad a + b : b :: c + d : d,$$

which was to be proved.

PROPOSITION VI. THEOREM.

If four quantities are in proportion, they are in proportion by division.

Assume the proportion,

$$a : b :: c : d, \quad \text{whence} \quad \frac{b}{a} = \frac{d}{c}, \quad . \quad . \quad . \quad (1)$$

subtracting each member of the preceding equation from 1, we have,

$$1 - \frac{b}{a} = 1 - \frac{d}{c}, \quad \text{or} \quad \frac{a-b}{a} = \frac{c-d}{c};$$

whence,

$$a : a - b :: c : c - d. \quad . \quad . \quad . \quad (3)$$

From (1) and (3) we have (P. 4, Cor.),

$$b : a - b :: d : c - d. \quad . \quad . \quad . \quad (4)$$

From (3) and (4) we have, by inversion,

$$a - b : a :: c - d : c, \quad \text{and} \quad a - b : b :: c - d : d,$$

which was to be proved.

PROPOSITION VII. THEOREM.

Equimultiples of two quantities are proportional to the quantities themselves.

Let ma and mb be any equimultiples of a and b ; we have,

$$\frac{mb}{ma} = \frac{b}{a} \quad \text{or} \quad ma : mb :: a : b,$$

which was to be proved.

Cor. Both terms of either couplet of a proportion may be multiplied or divided by the same quantity.

PROPOSITION VIII. THEOREM.

In a continued proportion, the sum of all the antecedents is to the sum of all the consequents as any antecedent is to the corresponding consequent.

Assume the continued proportion,

$$a : b :: c : d :: e : f, \quad \text{or,} \quad \frac{b}{a} = \frac{d}{c} = \frac{f}{e}; \dots (1)$$

we have

$$\frac{b}{a} = \frac{b}{a}, \quad \text{or,} \quad ab = ba, \quad \dots \dots (2)$$

$$\frac{b}{a} = \frac{d}{c}, \quad \text{or,} \quad cb = da, \quad \dots \dots (3)$$

$$\frac{b}{a} = \frac{f}{e}, \quad \text{or,} \quad eb = fa; \quad \dots \dots (4)$$

adding (2), (3), and (4), member to member, and factoring, we have,

$$(a + c + e) b = (b + d + f) a \dots \dots (5)$$

From (5), we have, (P. 3),

$$a + c + e : b + d + f :: a : b.$$

which was to be proved.

Scho. The demonstration may be extended to cases in which there is any number of couplets.

PROPOSITION IX. THEOREM.

If the corresponding terms of two proportions are multiplied together, the products will be in proportion.

Assume the proportions,

$$a : b :: c : d, \text{ or, } \frac{b}{a} = \frac{d}{c} (1)$$

and $e : f :: g : h, \text{ or, } \frac{f}{e} = \frac{h}{g} (2)$

Multiplying (1) and (2), member by member, we have,

$$\frac{bf}{ae} = \frac{dh}{cg}, \text{ or, } ae : bf :: cg : dh,$$

which was to be proved.

Cor. If four terms are in proportion, their squares are in proportion.

Scho. The principle above demonstrated may be extended to any number of proportions.

PROPOSITION X. THEOREM.

If lines parallel to any side of a triangle divide one of the other sides into equal parts, they will also divide the remaining side into equal parts.

Let EF and GH, parallel to the side AC of the triangle ACD, divide AD into equal parts, AE, EG, and GD; then will they divide CD into equal parts, CF, FH, and HD.

Through H draw HM parallel to DA.

Because MH and EG are parallels between parallels they are equal (P. 26, Cor. 1, B. 1); but EG is equal to GD; hence, MH is equal to GD. Because MH and GD are parallel, the angles FHM and HDG are opposite exterior and

interior angles; they are therefore equal. Because the angles HMF and DGH have their sides parallel and lying in the same direction they are equal (P. 23, B. 1). The triangles MFH and GHD have therefore two angles and their included side equal, each to each; consequently the triangles are equal in all their parts (P. 10, B. 1): hence, FH is equal to HD. In like manner, it may be shown that CF is equal to HD; the parts CF, FH, and HD are therefore equal to each other, *which was to be proved.*

Scho. The demonstration may be extended to the case in which parallels divide AD into any number of equal parts.

PROPOSITION XI. THEOREM.

A line parallel to any side of a triangle divides the other sides into proportional parts.

Let EF be parallel to AC, in the triangle ACD; then will AE and ED be proportional to CF and FD.

1°. Let AE and ED be to each other as two whole numbers, say as 2 is to 3. Divide AE into two, and ED in three equal parts; these will all be equal to each other; then through each point of division draw a line parallel to AC. These lines will divide CF into two and FD into three parts, all of which will be equal (P. 10, *Scho.*); hence,

$$CF : FD :: 2 : 3;$$

but,

$$AE : ED :: 2 : 3;$$

hence (P. 4), we have,

$$AE : ED :: CF : FD,$$

which was to be proved.

2°. Let AE and ED be incommensurable. Divide AE into m equal parts, m being any whole number; let one of these parts be applied to ED and suppose that it is contained in ED n times with a remainder less than that part; then will

$$\frac{ED}{AE} = \frac{n}{m} \text{ to within less than } \frac{1}{m}. \quad (1)$$

Through the points of division on AD draw lines parallel to AC; the lines between A and E will divide CF into m equal parts and those between E and D will divide FD into n equal parts with a remainder less than one of these parts; hence,

$$\frac{FD}{CF} = \frac{n}{m} \text{ to within less than } \frac{1}{m}. \quad (2)$$

Because m is any whole number the true values of the ratios $\frac{ED}{AE}$ and $\frac{FD}{CF}$ are equal to each other (P. 1, Cor.); hence,

$$\frac{ED}{AE} = \frac{FD}{CF}, \text{ or, } AE : ED :: CF : FD. \quad (3)$$

which was to be proved.

Cor. 1. Transforming proportion (3) by composition, remembering that $AE + ED = AD$ and $CF + FD = CD$, we have

$$AD : ED :: CD : FD, \quad (4)$$

$$\text{and} \quad AD : AE :: CD : CF; \quad (5)$$

whence, by alternation,

$$AD : CD :: ED : FD, \quad (6)$$

$$\text{and} \quad AD : CD :: AE : CF. \quad (7)$$

Cor. 2. The lines AC and EF are proportional to AD and

ED, and consequently to CD and FD. For, draw EK parallel to DC: then will KC be equal to EF, and we shall have (*Cor. 1*),

$$AD : ED :: AC : KC, \text{ or } EF;$$

but, $AD : ED :: CD : FD$;

hence, $AC : EF :: CD : FD$.

Cor. 3. If EF, GH, and KL are parallel to AC, they divide AD and CD proportionally. For, from (3), taken by inversion, we have,

$$ED : AE :: FD : CF, \dots\dots\dots (8)$$

and from *Cor. 2*, we have,

$$ED : EG :: FD : FH; \dots\dots\dots (9)$$

From (8) and (9), we have (*P. 4, Cor.*),

$$AE : EG :: CF : FH.$$

In like manner, we have,

$$EG : GK :: FH : HL,$$

and so on.

PROPOSITION XII. THEOREM.

If a line cuts two sides of a triangle proportionally it is parallel to the third side.

Let EF cut the sides AD and CD, of the triangle ACD, so that

$$AE : ED :: CF : FD; \dots\dots (1)$$

then is EF parallel to AC.

To prove the proposition, suppose that EF is not parallel to AC, but that some other line through E, as EG, is parallel to AC; then from *P. 11*, we shall have

$$AE : ED :: CG : GD. \dots\dots\dots (2)$$

Comparing (1) and (2), (P. 4), we have

$$CF : FD :: CG : GD.$$

Whence, by alternation,

$$CF : CG :: FD : GD. \quad . \quad . \quad . \quad . \quad . \quad (3)$$

In proportion (3), CF is greater than CG and FD is less than GD , which is impossible (P. 3, *Cor.* 2); hence, the supposition that led to proportion (3) is false; its contradictory must therefore be true, that is, EF is parallel to AC , *which was to be proved.*

Definition.

76. If two lines cut a third line in two points, the part of the third line included between the first two is called an **intercept**.

PROPOSITION XIII. THEOREM.

If several lines radiating from a point cut two parallel lines the corresponding intercepts are proportional.

Let the lines AC , AD , AE , and AT , radiating from A , cut the parallel lines CT and GL ; then we shall have

$$CD : DE : ET :: GH : HK : KL$$

From the triangles CDA and GHA , we have (P. 11, *Cor.* 2),

$$DA : HA :: CD : GH, \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and from the triangles DEA and HKA we have

$$DA : HA :: DE : HK. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

From (1) and (2) we have

$$CD : GH :: DE : HK.$$

In like manner it may be shown that

$$DE : HK :: ET : KL.$$

Hence,

$$CD : DE : ET :: GH : HK : KL,$$

which was to be proved.

Scho. The demonstration holds good where there is any number of radiating lines.

PROPOSITION XIV. THEOREM.

The bisectrix of any angle of a triangle divides the opposite side into segments proportional to the adjacent sides.

Let DK bisect the angle CDA of the triangle ACD ; then

$$AK : KC :: AD : CD.$$

Prolong CD till DE is equal to DA, and draw EA. Because DE and DA are equal, the triangle ADE is isosceles and consequently the angles EAD and DEA are equal. But, CDA being an exterior angle of the triangle ADE is equal to the sum of the opposite interior angles EAD and DEA ; consequently half of CDA, or CDK, is equal to the angle DEA ; hence, DK is parallel to EA. We have, therefore, from P. 11,

$$AK : KC :: ED : DC.$$

Substituting AD for ED, we have,

$$AK : KC :: AD : CD,$$

which was to be proved.

Scho. The converse of this proposition may be proved in a manner entirely similar to that followed in P. 12.

Definitions.

77. Two polygons are **similar** when their corresponding angles are equal and when the sides about these angles taken in the same order are proportional. Corresponding lines of two similar polygons are called **homologous** lines ; corresponding angles are called **homologous** angles.

PROPOSITION XV. THEOREM.

If the corresponding angles of two triangles are equal the triangles are similar.

In the triangles $\triangle ACD$ and $\triangle POR$ let the angles P , O , and R be respectively equal to the angles A , C , and D ; then are the triangles similar.

Because the corresponding angles are equal, it only remains to be shown that the sides taken in the same order are proportional.

Suppose DA to be greater than RP . Place the triangle POR on ACD so that the angle R shall coincide with D , P falling at E and O at F . Then because the angle DEF is equal to the angle A , EF is parallel to AC , and from P. 11, Cor. 2, we have

$$AC : CD : DA :: EF : FD : DE,$$

or, $AC : CD : DA :: PO : OR : RP$,
which was to be proved.

Cor. 1. If two triangles have two angles of the one respectively equal to two angles of the other, the triangles are similar.

Cor. 2. If two triangles have their corresponding sides parallel or perpendicular, each to each, the triangles are similar.

PROPOSITION XVI. THEOREM.

If two triangles have an angle in each equal and the including sides proportional, the triangles are similar.

In the triangles $\triangle ACD$ and $\triangle POR$ let the angles R and D be equal, and let the sides CD and DA be proportional to OR and RP ; then are the triangles similar.

Place the triangle POR on the

triangle ACD so that the angle R shall coincide with D, the vertex P falling at E and the vertex O at F. Then, because DC and DA are proportional to DF and DE, EF is parallel to AC (P. 12); hence, the angle EFD, or O, is equal to C, and DEF, or P, is equal to A; the given triangles are therefore mutually equiangular, and consequently similar, *which was to be proved.*

PROPOSITION XVII. THEOREM.

If the three sides of one triangle are proportional to the three sides of another triangle, the triangles are similar.

In the triangles ACD and POR, let AC, CD, and DA be proportional to PO, OR, and RP; then are the triangles similar.

Lay off DE equal to RP, DF equal to RO, and draw EF.

Then, because DA and DC are proportional to DE and DF, the line EF is parallel to AC (P. 12), and the triangles ACD and EFD are similar (P. 16). From P. 11, *Cor.* 2, we have

$$AC : CD :: EF : FD; \dots \dots \dots (1)$$

but by hypothesis, we have,

$$AC : CD :: PO : OR, \text{ or } FD. \dots \dots \dots (2)$$

Because proportions (1) and (2) have three corresponding terms equal, each to each, their other terms must be equal, that is, EF is equal to PO; hence, the triangles POR and EFD have their sides respectively equal; they are therefore equal in all their parts: but ACD and EFD are similar; hence, ACD and POR are similar, *which was to be proved.*

PROPOSITION XVIII. THEOREM.

If a line is drawn from the vertex of the right angle of a right-angled triangle perpendicular to the hypotenuse :

1°. *It will divide the triangle into two triangles that are similar to the given triangle and to each other ;*

2°. *It will be a mean proportional between the segments into which it divides the hypotenuse ;*

3°. *Either side about the right angle will be a mean proportional between the entire hypotenuse and the adjacent segment.*

Let ACD be a triangle, right-angled at D, and let DE be perpendicular to the hypotenuse AC.

1°. The triangles DCE and ACD have the angle C common, and the angles CED and CDA equal, because both are right angles ; hence, DCE is similar to ACD (P. 15, Cor. 1). For like reasons, the triangle ADE is similar to ACD ; and because both DCE and ADE are similar to ACD, they are similar to each other, *which was to be proved.*

2°. Because DCE and ADE are similar, the angles DCE and ADE being homologous, we have,

$$AE : DE :: DE : CE,$$

which was to be proved.

3°. Because the triangles ACD and DCE are similar, the angle C being common, we have,

$$AC : CD :: CD : CE;$$

and because ACD and ADE are similar, the angle A being common, we have

$$AC : AD :: AD : AE,$$

which was to be proved.

Cor. From any point D on a semi-circumference let a perpendicular DE be drawn to the diameter, and also chords DA and DC to the extremities of the diameter; then will ACD be a right-angled triangle, and from what was proved above we infer that the perpendicular is a mean proportional between the segments into which it divides the diameter, and that each chord is a mean proportional between the whole diameter and the adjacent segment.

PROPOSITION XIX. THEOREM.

If two chords intersect within a circumference, they divide each other into segments that are inversely proportional.

Let the chords AC and DE intersect at Q; then are their segments inversely proportional, that is, one segment of the first is to one segment of the second as the remaining segment of the second is to the remaining segment of the first.

Draw AD and CE.

The triangles ADQ and ECQ have the angles at Q equal because they are opposite or vertical angles, and the angles D and C equal because each is measured by half the arc AE; consequently, the triangles are similar (P. 15, *Cor.* 1); hence

$$AQ : DQ :: QE : QC,$$

which was to be proved.

PROPOSITION XX. THEOREM.

If two secants intersect without a circumference, the entire secants are inversely proportional to their external segments.

Let the secants AC and AD intersect at A; then are they inversely proportional to their external segments.

Draw CF and DE.

The triangles ACF and ADE have the angle A common, and the angles C and D equal, because each is measured by half the arc FE; these triangles are therefore similar: hence,

$$AC : AD :: AF : AE, \dots (1)$$

which was to be proved.

Cor. If the secant AD is revolved about A, towards AK, the points D and F approach each other, and when AD becomes a tangent, the two points coincide at the point of contact K. In this case, proportion (1) becomes

$$AC : AK :: AK : AE;$$

that is, *a tangent is a mean proportional between the entire secant and its external segment.*

PROPOSITION XXI. THEOREM.

The perimeters of two similar polygons are to each other as any two homologous sides.

Let ACDE and PQRS be two similar polygons, in which the angles A, C, D, and E, are respectively equal to P, Q, R, and S; then from the definition of similar polygons, we have

$$AC : CD : DE : EA :: PQ : QR : RS : SP; \dots (1)$$

from (1), we have, by P. 8,

$$AC + CD + DE + EA : PQ + QR + RS + SP :: AC : PQ, \&c.,$$

which was to be proved.

Cor. The perimeters of similar polygons are proportional to any homologous diagonals, or to any other homologous lines.

EXERCISES ON BOOK III.

Let the student demonstrate the following theorems:

1°. If DE bisects the external angle ADF of the triangle ACD, show that

$$EA : EC :: AD : CD.$$

2°. Show that the bases of two similar triangles are to each other as the distances of these bases from the opposite vertices.

3°. Show that homologous diagonals of similar polygons are proportional to any two homologous sides.

4°. If several parallels are cut by two lines intersecting at a point, show that the intercepts are proportional to their distances from the point of intersection.

5°. If a chord is drawn through a fixed point within a circumference, show that the product of its two segments is always the same, no matter what may be the direction of the chord.

APPLICATION OF PRECEDING PRINCIPLES TO THE CONSTRUCTION OF PROBLEMS.

PROBLEM I.

To divide a given line into any number of equal parts.

Let it be required to divide AE into three equal parts. From A draw any other line, and on it lay off AK, KL, and LM, each equal to any assumed line; join

M and E, and draw LD and KC, parallel to ME: then will AC, CD, and DE be the required parts of AE. (P. 10).

Scho.—The method of proceeding is the same, when it is required to divide AE into any number of equal parts.

PROBLEM II.

To divide a given line into parts proportional to any given lines.

Let it be required to divide AE into parts proportional to the lines P, Q, and R. From A draw any line and on it lay off $AK = P$, $KL = Q$, and $LM = R$; join M and E, and draw LD and KC parallel to ME: then will AC, CD, and DE, be the required parts (P. 11, Cor. 3).

Scho.—The method is the same when there are any number of required parts.

PROBLEM III.

To find a fourth proportional to three given lines.

Let it be required to find a fourth proportional to P, Q, and R.

From A draw two lines, making any angle with each other; on these lay off $AE = P$, $EC = Q$, and $AF = R$; join E and F, and draw CD parallel to EF: then will FD be the required fourth proportional. For, from P. 11, we have,

$$AE : EC :: AF : FD,$$

or

$$P : Q :: R : FD.$$

Cor. If $Q = R$, FD is a third proportional to P and Q.

PROBLEM IV.

To construct a mean proportional between two given lines.

Let it be required to construct a mean proportional between P and Q. On an indefinite line AC lay off $AE = P$ and $EC = Q$. On AC as a diameter construct a semi-circumference and from E draw a perpendicular to AC, meeting the semi-circumference at D; then is ED the required mean proportional. For, from P. 18, *Cor.*, we have

$$AE : ED :: ED : CE,$$

or

$$P : ED :: ED : Q.$$

PROBLEM V.

To divide a given line so that the greater part shall be a mean proportional between the whole line and the less part.

Let CA be the given line. At A draw AD perpendicular to AC and lay off AD equal to half of AC; from D as a centre with DA as a radius draw the circumference AEF, also draw the secant CDE; the circumference will be tangent to CA at A and its diameter FE will be equal to CA. From C as a centre with CF as a radius draw an arc cutting CA at G; then will G be the required point of division. For from P. 20, *Cor.*, we have

$$CE : CA :: CA : CF.$$

Whence, by division,

$$CE - CA : CA :: CA - CF : CF; \quad . \quad . \quad (1)$$

but $CE - CA = CF$, or CG , $CA - CF = CA - CG = GA$,
and $CF = CG$; substituting these in (1), we have,

$$CG : CA :: GA : CG,$$

whence, *by inversion*,

$$CA : CG :: CG : GA.$$

The segment CG is the greater, because $CA > CG$.

Scho. The line CA is said to be divided in **extreme and mean ratio** at the point G .

PROBLEM VI.

To draw a line through a given point within a given angle so that the parts between that point and the sides of the angle shall be equal.

Let P be the given point and ACD the given angle.

Draw PQ parallel to AC cutting CD at Q ; lay off QR equal to CQ and draw RPA ; then will RA be the required line.

Note. Let the student show that $RP = PA$.

BOOK IV.

MEASURE AND COMPARISON OF AREAS.

Definitions and Explanations.

78. The unit of measure of a surface is a square described on the linear unit as a side; thus, if the linear unit is a *foot*, the unit of surface is a *square foot*.

A unit of surface is sometimes called a superficial unit.

79. The area of a surface is an expression for the surface in terms of a superficial unit.

80. The product of two lines is *the number of times* the linear unit is contained in one line, multiplied by *the number of times* the same unit is contained in the other line; the unit of the product is a superficial unit.

The operation of comparing two surfaces is purely *numerical*. In what follows, we shall regard two surfaces as *equal* when they have the same area; if they can be made to coincide throughout they are said to be *equal in all their parts*.

81. The altitude of a triangle is the perpendicular from the vertex of any angle of the triangle to the opposite side, or to the opposite side prolonged; the vertex considered is called the **vertex of the triangle**, and the opposite side is called the **base of the triangle**.

82. The altitude of a parallelogram, or of a trapezoid, is the perpendicular distance between two parallel

sides; the sides considered are called bases, one being the lower base and the other the upper base.

In a parallelogram either pair of parallel sides may be taken as bases.

PROPOSITION I. THEOREM.

If two rectangles have equal altitudes they are to each other as their bases.

Let the altitudes CD and LM of the rectangles CE and LN be equal; then are the rectangles proportional to AC and KL .

1°. Let the bases be to each other as two whole numbers, say as 3 is to 4.

Divide AC into three equal parts and KL into four equal parts, then at the points of division draw lines perpendicular to the corresponding bases. These lines will divide the rectangle CE into three partial rectangles, and the rectangle LN into four partial rectangles, all of which are equal to each other (P. 26, Cor. 4, B. 1); hence

$$ACDE : KLMN :: 3 : 4, \quad \dots \dots (1)$$

but, $AC : KL :: 3 : 4; \quad \dots \dots (2)$

hence, from proportions (1) and (2), (P. 4, B. 3), we have

$$ACDE : KLMN :: AC : KL,$$

which was to be proved.

2°. Let the bases be incommensurable.

Let AC be divided into m equal parts; let one of these parts be applied to KL and suppose that it is contained in KL , n times, with a remainder less than that part; then will

$$\frac{KL}{AC} = \frac{n}{m} \text{ to within less than } \frac{1}{m}. \quad . \quad . \quad . \quad (1)$$

At each point of division on AC and KL, let lines be drawn respectively perpendicular to the bases. These will divide the rectangle CE into m equal rectangles, and the rectangle LN into n corresponding and equal rectangles, with a remainder less than one of these rectangles; hence,

$$\frac{KLMN}{ACDE} = \frac{n}{m} \text{ to within less than } \frac{1}{m}. \quad . \quad . \quad . \quad (2)$$

But m is any whole number; hence, the true values of the ratios given by equations (1) and (2) are equal to each other, (P. 1, Cor., B. 3); that is,

$$\frac{KLMN}{ACDE} = \frac{KL}{AC}, \text{ or } ACDE : KLMN :: AC : KL,$$

which was to be proved.

PROPOSITION II. THEOREM.

The area of a rectangle is equal to the product of its base and altitude.

Let AD be a rectangle and AL the assumed superficial unit, that is, a square each of whose sides is equal to a linear unit; let the square AL be so placed that AK shall be on the prolongation of CA, and AM on the prolongation of EA. Prolong DE and LK till they meet at F, forming the rectangle AF. Now, if we take AC and AK as bases, the rectangles AD and AF will have the same altitude AE, and we shall have, (P. 1),

$$ACDE : AEFK :: AC : AK; \quad . \quad . \quad . \quad (1)$$

if we take AE and AM as bases, the rectangles AF and AL will have the same altitude AK, and we shall have

$$AEFK : AKLM :: AE : AM; \dots (2)$$

multiplying proportions (1) and (2) together, term by term (P. 9, B. 3), and dividing both terms of the first couplet of the resulting proportion by AEFK, we have

$$ACDE : AKLM :: AC \times AE : AK \times AM.. \therefore (3)$$

But AK and AM are each equal to the linear unit, and AKLM is equal to the superficial unit. Passing to numerical values, proportion (3) becomes,

$$ACDE : 1 :: AC \times AE : 1, \text{ or } ACDE = AC \times AE,$$

that is, the number of superficial units in the rectangle is equal to the number of linear units in its base multiplied by the number of linear units in its altitude, *which was to be proved*.

Cor. Any two rectangles are to each other as the products of their bases and altitudes; if their bases are equal, they are to each other as their altitudes.

Scho. The product of two lines is often called the rectangle of the lines, because the product expresses the area of a rectangle whose adjacent sides are the given lines.

PROPOSITION III. THEOREM.

The area of a parallelogram is equal to the product of its base and altitude.

Let ACDE be a parallelogram; draw AL and CK perpendicular to AC meeting ED, and ED prolonged at L and K: then, is the area of the parallelogram equal to the product of AC and CK.

The triangles ALE and CKD, have AE parallel and equal to CD, AL parallel and equal to CK, and the included angle A equal to the included angle C; they are therefore equal in all their parts. If we now add to the figure ACDL the tri-

angle CKD, we shall have the rectangle ACKL; if we add to the figure ACDL the equal triangle ALE we shall have the parallelogram ACDE; hence, the rectangle CL is equal to the parallelogram CE (Ax. 2). But the area of the rectangle is equal to the product of AC and CK; hence, the area of the parallelogram is also equal to the product of AC and CK, *which was to be proved.*

Cor. Any two parallelograms are to each other as the products of their bases and altitudes. If their bases are equal, they are to each other as their altitudes; if their altitudes are equal, they are to each other as their bases.

PROPOSITION IV. THEOREM.

The area of a triangle is equal to half the product of its base and altitude.

Let ACD be any triangle, and let DE be its altitude: then is the area of the triangle equal to $\frac{1}{2}$ ($AC \times DE$).

Through D draw DK parallel to CA and through A draw AK parallel to CD; the figure ACDK is then a parallelogram equal to twice the given triangle (P. 26, Cor. 2, B. 1). But, the area of the parallelogram is equal to $AC \times DE$; hence, the area of the triangle is $\frac{1}{2}$ ($AC \times DE$), *which was to be proved.*

Cor. 1. Any two triangles are to each other as the products of their bases and altitudes; if their altitudes are equal, they are to each other as their bases; if their bases are equal, they are to each other as their altitudes.

Cor. 2. If two triangles have a common base and if their vertices are on a line parallel to that base they are equal.

Cor. 3. If a triangle has the same base as a parallelogram

and if the vertex of the triangle is on the opposite base, or on that base produced, the triangle is equal to half the parallelogram.

PROPOSITION V. THEOREM.

The area of a trapezoid is equal to the product of its altitude, and the half sum of its parallel bases.

Let ACDE be any trapezoid, and let DK be its altitude: then is the area of the trapezoid equal to

$$DK \times \frac{1}{2}(AC + DE).$$

Draw AD dividing the trapezoid into two triangles; the altitude of each triangle is equal to DK. Now, the area of ACD is equal to $\frac{1}{2}AC \times DK$, and the area of ADE is equal to $\frac{1}{2}DE \times DK$ (P. 4); hence, the area of the trapezoid is equal to

$$\frac{1}{2}AC \times DK + \frac{1}{2}DE \times DK, \text{ or to } DK \times \frac{1}{2}(AC + DE).$$

which was to be proved.

PROPOSITION VI. THEOREM.

The square of the sum of two lines is equal to the sum of the squares of the lines, increased by twice their rectangle.

Let AC and CD be any two lines, CD lying in the prolongation of AC: then is

$$(AC + CD)^2 = \overline{AC}^2 + \overline{CD}^2 + 2AC \times CD.$$

On AD construct the square AE, and on AC construct the square AK; then prolong CK to N and LK to M.

Because CK and KL are each equal to AC, KN and KM are each equal to CD; hence, the measure of each of the rectangles CM and KF is $AC \times CD$, and the measure of the

square KE is \overline{CD}^2 . But the square AE is made up of the squares AK and KE, together with the rectangles CM and KF; hence,

$$(AC + CD)^2 = \overline{AC}^2 + \overline{CD}^2 + 2AC \times CD,$$

which was to be proved.

Cor. If AC is equal to CD the four parts into which AE is divided are equal squares; hence, the square of a given line is equal to four times the square of half that line.

PROPOSITION VII. THEOREM.

The square of the difference of two lines is equal to the sum of the squares of the lines, diminished by twice their rectangle.

Let AC and DC be two lines placed as shown in the figure; then is

$$(AC - CD)^2 = \overline{AC}^2 + \overline{CD}^2 - 2AC \times CD.$$

On AC construct the square AE; lay off FK equal to CD, and on it construct the square KM; draw DP parallel to CE and prolong LK to N.

Because LN is equal to AC and LM to CD, the rectangle NM is equal to the rectangle DE, and each is measured by $AC \times CD$. If now from the entire figure CM, which is equal to the sum of the squares AE and KM, we take away the rectangles NM and DE, there will remain the square AN, that is, the square on $AC - CD$; hence,

$$(AC - CD)^2 = \overline{AC}^2 + \overline{CD}^2 - 2AC \times CD,$$

which was to be proved.

PROPOSITION VIII. THEOREM.

The square of the hypotenuse of a right-angled triangle is equal to the sum of the squares of the other two sides.

Let ACD be a right-angled triangle, AC being the hypotenuse and D the right angle; then is

$$\overline{AC}^2 = \overline{CD}^2 + \overline{DA}^2.$$

Prolong CD till DE is equal to AD , and complete the square AE ; prolong AD till DP is equal to CD , and complete the square DQ ; also, on AC construct the square AK . Then draw DM perpendicular to KL ; also draw CF and DL .

The triangles ALD and ACF have the angles DAL and FAC equal, because each is equal to DAC increased by a right angle; they also have AL equal to AC , because they are sides of the square AK , and DA equal to FA , because they are sides of the square AE ; hence, the triangles are equal (P. 8, B. 1).

But the triangle ALD is half the rectangle AM , and the triangle ACF is half the square AE (P. 4, Cor. 3); hence, the rectangle AM is equal to the square AE . In like manner it may be shown that the rectangle CM is equal to the square DQ . But, the sum of the rectangles AM and CM is equal to the square AK ; hence,

$$\overline{AC}^2 = \overline{CD}^2 + \overline{DA}^2, \quad (1)$$

which was to be proved.

Cor. 1. From equation (1), we have,

$$\overline{CD}^2 = \overline{AC}^2 - \overline{DA}^2 \text{ and } \overline{DA}^2 = \overline{AC}^2 - \overline{CD}^2.$$

Cor. 2. If $CD = DA$, they form the adjacent sides of a square whose diagonal is AC . In this case

$$\overline{AC}^2 = 2\overline{CD}^2 \text{ whence } AC = \sqrt{2} \times CD.$$

Whence by P. 3, B. 3, we have,

$$AC : CD :: \sqrt{2} : 1 ;$$

that is, the diagonal of a square is to one of the sides as $\sqrt{2}$ is to 1.

PROPOSITION IX. THEOREM.

In any triangle, the square of a side opposite an acute angle is equal to the sum of the squares of the other sides, diminished by twice the rectangle of the base and the distance from the vertex of the acute angle to the foot of the perpendicular drawn from the vertex of the triangle to the base, or to the base produced.

In the triangle ACD , let AC be the base, D the vertex, and DE a perpendicular from D to AC , or to AC prolonged; also let A be an acute angle; then is

$$\overline{CD}^2 = \overline{DA}^2 + \overline{AC}^2 - 2AC \times AE.$$

Because CE is equal to the difference between AC and AE , we have (P. 7),

$$\overline{CE}^2 = \overline{AE}^2 + \overline{AC}^2 - 2AC \times AE; \therefore (1)$$

adding \overline{ED}^2 to both members of (1), we have,

$$\overline{CE}^2 + \overline{ED}^2 = (\overline{AE}^2 + \overline{ED}^2) + \overline{AC}^2 - 2AC \times AE;$$

substituting for $\overline{CE}^2 + \overline{ED}^2$ its value \overline{CD}^2 , and for $\overline{AE}^2 + \overline{ED}^2$ its value \overline{DA}^2 (P. 8), we have,

$$\overline{CD}^2 = \overline{DA}^2 + \overline{AC}^2 - 2AC \times AE,$$

which was to be proved.

PROPOSITION X. THEOREM.

In any obtuse-angled triangle, the square of the side opposite the obtuse angle is equal to the sum of the squares of the other two sides, increased by twice the rectangle of the base and the distance from the vertex of the obtuse angle to the foot of the perpendicular drawn from the vertex of the triangle to the base produced.

In the obtuse-angled triangle ACD, let AC be the base, D the vertex, and DE a perpendicular from D to CA produced; also let A be the obtuse angle; then is

$$\overline{CD}^2 = \overline{DA}^2 + \overline{AC}^2 + 2AE \times AC.$$

Because CE is equal to the sum of AE and AC, we have (P. 6),

$$\overline{CE}^2 = \overline{AE}^2 + \overline{AC}^2 + 2AE \times AC; \quad . \quad . \quad (1)$$

adding \overline{ED}^2 to both members of (1), we have,

$$\overline{CE}^2 + \overline{ED}^2 = (\overline{AE}^2 + \overline{ED}^2) + \overline{AC}^2 + 2AE \times AC;$$

substituting for $\overline{CE}^2 + \overline{ED}^2$ its value \overline{CD}^2 , and for $\overline{AE}^2 + \overline{ED}^2$ its value \overline{AD}^2 (P. 8), we have

$$\overline{CD}^2 = \overline{DA}^2 + \overline{AC}^2 + 2AE \times AC,$$

which was to be proved.

Scho. The right-angled triangle is the only one in which the sum of the squares of two sides is equal to the square of the third side.

PROPOSITION XI. THEOREM.

If two triangles have an angle in each equal, the triangles are to each other as the products of the including sides.

Let the triangles ACD and PQR have the angles D and R equal: then

$$ACD : PQR :: CD \times DA : QR \times RP.$$

Place the triangle PQR on the triangle ACD so that the angle R shall coincide with the angle D, P falling at E, and Q at F; draw FA.

The triangles ACD and AFD, have their bases CD and FD in the same line and their vertices at the same point A; hence, they have the same altitude; they are therefore proportional to their bases (P. 4, Cor. 1), that is,

$$ACD : AFD :: CD : FD. \quad . \quad . \quad . \quad (1)$$

The triangles AFD and EFD have their bases DA and DE in the same line and their vertices at the same point F; hence, they have the same altitude; they are therefore proportional to their bases, that is,

$$AFD : EFD :: DA : DE. \quad . \quad . \quad . \quad (2)$$

Multiplying (1) by (2), term by term, (P. 9, B. 3), and then

dividing both terms of the first couplet of the resulting proportion by AFD , (P. 7, *Cor.*, B. 3), we have,

$$\begin{aligned} ACD : EFD &:: CD \times DA : FD \times DE, \\ \text{or, } ACD : PQR &:: CD \times DA : QR \times RP, \quad . \quad . \quad (3) \end{aligned}$$

which was to be proved.

Cor. 1. If CD and DA are proportional to QR and RP , the triangles ACD and PQR will be similar, and we shall have

$$DA : CD :: RP : QR, \text{ or } \frac{CD}{DA} = \frac{QR}{RP} \quad . \quad . \quad (4)$$

Multiplying the first term of the second couplet of (3) by $\frac{CD}{DA}$, and the second term of that couplet by the equal quantity $\frac{QR}{RP}$, and reducing, we have

$$ACD : PQR :: \overline{CD}^2 : \overline{QR}^2.$$

But,

$$\overline{CD}^2 : \overline{QR}^2 :: \overline{DA}^2 : \overline{RP}^2 :: \overline{AC}^2 : \overline{PQ}^2.$$

Hence, *two similar triangles are to each other as the squares of any two homologous sides.*

Cor. 2. If ACD and PQR are similar, ACD and EFD are also similar; consequently the second couplets of (1) and (2) are equal; hence,

$$ACD : AFD :: AFD : EFD,$$

that is, AFD is a mean proportional between ACD and EFD .

PROPOSITION XII. THEOREM.

Two similar polygons may be divided into the same number of similar triangles, similarly placed.

Let ACDEF and PQRST be similar polygons, the equal angles in both being taken in the order named. Draw the diagonals AD and AE, also the diagonals PR and PS; then will the corresponding triangles of the polygons be similar.

The angle C is equal to the angle Q, and from the definition of similar polygons AC and CD are proportional to PQ and QR; hence, the triangles ACD and PQR are similar (P. 16, B. 3).

Because ACD and PQR are similar, the angle CDA is equal to QRP, and the sides DA and RP are proportional to CD and QR, and consequently to DE and RS. If we take the equal angles CDA and QRP from the equal angles CDE and QRS, the remaining angles ADE and PRS are equal. Consequently, the triangles ADE and PRS have an angle in each equal, and their including sides proportional; hence, their triangles are similar. In like manner it may be shown that AEF and PST are similar. Hence, the corresponding triangles of the two polygons are similar, *which was to be proved.*

Cor. 1. Any two corresponding triangles are like parts of the polygons to which they belong. For, the triangles ACD and PQR, being similar, are proportional to \overline{AD}^2 and \overline{PR}^2 , and the triangles ADE and PRS being similar are also proportional to \overline{AD}^2 and \overline{PR}^2 ; consequently ACD and PQR are proportional to ADE and PRS. In like manner it may be

shown that ADE and PRS are proportional to AEF and PST.
Hence,

$$ACD : ADE : AEF :: PQR : PRS : PST. \quad (1)$$

Now, the sum of the antecedents of (1) is equal to the first polygon, and the sum of the consequents of (1) is equal to the second polygon. Hence, from P. 8, B. 3, we infer that *the first polygon is to the second, as any triangle in the first is to the corresponding triangle in the second.*

Cor. 2. From the preceding corollary, it follows that two similar polygons are to each other as the squares of any two homologous sides of any two corresponding triangles; but, the homologous sides of the corresponding triangles are the homologous sides or the homologous diagonals of the polygons to which the triangles belong; *hence, two similar polygons are to each other as the squares of their homologous sides, or as the squares of their homologous diagonals.*

EXERCISES ON BOOK IV.

Let the student demonstrate the following theorems:

1°. *The area of a triangle is equal to half the product of its perimeter and the radius of the inscribed circle.*

2°. *The rectangle of the sum and the difference of two lines is equal to the difference of their squares.*

3°. *The sum of the squares of two sides of a triangle is equal to twice the square of half the third side, increased by twice the square of the line drawn from the middle of the third side to the opposite vertex.*

4°. *The sum of the squares of the diagonals of a parallelogram is equal to the sum of the squares of its sides.*

5°. *If lines are drawn from any point to the vertices of a rectangle, the sum of the squares of the lines to the extremi-*

ties of one diagonal is equal to the sum of the squares of the lines to the extremities of the other diagonal.

6°. *If a line is drawn from the centre of a circle to any point of any chord, the square of this line, increased by the rectangle of the segments of the chord, is equal to the square of the radius.*

APPLICATION OF PRECEDING PRINCIPLES TO THE SOLUTION OF PROBLEMS.

PROBLEM I.

To construct a square equal to the sum of two given squares; also, to construct a square equal to the difference of two given squares.

Let AC and PQ be sides of the given squares, AC being the greater.

1°. Draw two lines KL and KN perpendicular to each other at K; lay off KL equal to AC and KN equal to PQ; draw LN and on it, as a side, construct the square LO; it will be equal to the sum of the given squares (P. 8).

2°. Draw two lines KL and KT perpendicular to each other at K; lay off KL equal to PQ; from L as a centre, with a radius equal to AC, draw an arc cutting KT at S, and on KS as a side construct the square KH; it will be equal to the difference of the given squares (P. 8, Cor. 1).

PROBLEM II.

To construct a triangle equal to a given polygon.

Let ACDEF be the given polygon.

Take AC as a base and prolong it in both directions; draw the diagonals AE and CE. Through F draw FG parallel to EA, and draw EG. Because the triangles AEF and AEG have the common base AE, and because their vertices F and G are on a line FG parallel to that base they are equal (P. 4, Cor. 2). If we take the triangle AEF from the given polygon and then add the equal triangle AEG, the resulting polygon GCDE will be equal to the given polygon. Again draw DK parallel to EC and join the points K and E. Because the triangles ECD and ECK have a common base EC, and because their vertices D and K are in the line DK parallel to that base, the triangles are equal. If we take from the polygon GCDE the triangle CDE, and add the equal triangle CKE, the resulting triangle KEG will be equal to the polygon GCDE, and consequently to the given polygon.

PROBLEM III.

To construct a square equal to a given triangle.

Let GKE be the given triangle, GK being its base and EF its altitude.

Construct a mean proportional CD between $\frac{1}{2}$ GK and FE (Prob. 4, B. 3); then, on CD as a side construct the square AD: it will be the required square; for,

$$AC^2 = \frac{1}{2}GK \times EF, \text{ (P. 2, and P. 4).}$$

Scho. By means of Problems 2 and 3 we can construct a square equal to a given polygon, and by the aid of Problem 1 we can construct a square equal to the sum, or to the difference of any two polygons.

PROBLEM IV.

To construct a polygon on a given line as a side, that shall be similar to a given polygon.

Let ACDEF be the given polygon and let PQ be the side which is to be homologous with AC; suppose PQ to be placed parallel to AC.

Draw AD and AE.

Draw QR parallel to CD, and PR parallel to AD, and let these lines intersect at R; then are the triangles ACD and PQR similar, (P. 15, *Cor.* 2, B. 3). Draw RS parallel to DE, and PS parallel to AE, and let these lines intersect at S; then are the triangles ADE and PRS similar. In like manner draw ST parallel to EF, and PT parallel to AF, and let these lines intersect at T; then are the triangles AEF and PST similar. From the similarity of the homologous triangles we infer the equality of the corresponding angles of the given polygon and of the polygon PQRST; we also infer the proportionality of their sides taken in the same order; hence, the polygon PQRST is similar to the given polygon.

BOOK V.

PROPERTIES AND MEASURE OF REGULAR POLYGONS AND CIRCLES. •

Definition.

83. A regular polygon is a polygon that is both *equilateral* and *equiangular*.

PROPOSITION I. THEOREM.

If two regular polygons have the same number of sides they are similar.

For, their corresponding angles are equal, because any angle of either is equal to twice as many right angles as the figure has sides, less four right angles, *divided* by the number of angles (P. 25, B. 1); furthermore, their corresponding sides are proportional, because all the sides of each polygon are equal to each other; hence, the polygons are similar, *which was to be proved*.

Cor. If two regular polygons have the same number of sides, their perimeters are proportional to any homologous lines, and their areas are proportional to the squares of these lines.

PROPOSITION II. THEOREM.

A circle can be circumscribed about any regular polygon ; a circle can also be inscribed within it.

Let ACDEF be a regular polygon. Bisect the angles A and C and suppose their bisectrices to meet at O ; from O, draw lines to the vertices, D, E, and F ; also draw OP, OQ, &c., perpendicular to the sides of the polygon.

1°. Because the angles A and C are equal, their halves are equal, that is, CAO and ACO are equal ; the triangle ACO is therefore isosceles ; hence, OC is equal to OA. The triangles ACO and CDO are equal, because OA is equal to OC, AC to CD, and the angle OAC to OCD ; hence, OD is equal to OC, and consequently to OA. In like manner it may be shown that OE and OF are each equal to OA. Hence, if a circumference is drawn from O as a centre and with OA as a radius it will pass through all the vertices of the polygon, that is, it will be circumscribed about the polygon, *which was to be proved.*

2°. Because the triangles ACO, CDO, &c., are equal, their altitudes OP, OQ, &c., are equal ; hence, if a circumference is drawn from O as a centre, with a radius OP, it will be tangent to all the sides of the polygon, that is, it will be inscribed within the polygon, *which was to be proved.*

PROPOSITION III. THEOREM.

If a circumference is divided into equal arcs, the corresponding chords will form a regular inscribed polygon ; and

if tangents are drawn at the middle points of each of these arcs, they will form a regular circumscribed polygon.

Let AHC , CKD , &c., be equal arcs of the circumference OA , and let H , K , &c., be their middle points.

Draw the chords AC , CD , DE , &c., forming an inscribed polygon, and at H , K , L , &c., draw tangents meeting at P , Q , R , &c., forming a circumscribed polygon.

1°. In the polygon $ACDEF$, the sides are equal, because they are chords of equal arcs; and the angles are equal because they are measured by halves of equal arcs; hence, the inscribed polygon is regular, *which was to be proved*.

2°. Because PN and PH are tangent to the circumference OA , the line OP bisects the angle NPH and also the angle NOH (Prob. 14, *Cor.*, B. 2); hence, OP passes through A , the middle of the arc NAH . In like manner it may be shown that each of the lines OQ , OR , &c., passes through the corresponding vertex of the inscribed polygon. In the similar triangles ACO and PQO , we have,

$$OC : OQ :: AC : PQ, \quad (1)$$

and in the similar triangles CDO and QRO , we have,

$$OC : OQ :: CD : QR; \quad (2)$$

from (1) and (2), we have,

$$AC : PQ :: CD : QR;$$

but, CD is equal to AC ; hence, QR is equal to PQ . In like manner it may be shown that RS is equal to QR , and conse-

quently to PQ; and so on; hence, the circumscribed polygon is equilateral. It is also equiangular; for each of its angles is equal to the corresponding angle of the inscribed polygon, because their sides are respectively parallel and lie in the same direction (P. 23, B. 1). Hence, the circumscribed polygon is both equilateral and equiangular; it is therefore regular, *which was to be proved*.

Cor. 1. The polygons ACDEF and PQRST are similar (P. 1).

Cor. 2. If a circumference is divided into equal arcs, the tangents drawn at the points of division, form a regular circumscribed polygon; hence, if tangents are drawn at the vertices of a regular inscribed polygon they will form a similar circumscribed polygon.

Cor. 3. If the arcs subtended by the sides of a regular inscribed polygon are bisected, the corresponding chords will form a regular inscribed polygon having double the number of sides.

Scho. If we have given a regular inscribed polygon we can always construct a similar circumscribed polygon. Then, by the methods already described, we may construct a regular inscribed and a regular circumscribed polygon, having double the number of sides. By repeating the process we may again double the number of sides, and so on, *ad infinitum*. This method of proceeding is called the *method of continued duplication*. Thus, if we start with an inscribed and a circumscribed square, we can find in succession, regular inscribed and circumscribed polygons, of 8, 16, 32, &c., sides.

Definitions.

84. The centre of a regular polygon is the common centre of the inscribed and circumscribed circles.

85. The radius of a regular polygon is a line drawn from the centre to any vertex.

86. The apothem of a regular polygon is perpendicular from the centre to any side.

87. The angle at the centre of a regular polygon is the angle between two radii drawn to the extremities of any side.

PROPOSITION IV. THEOREM.

The area of a regular polygon is equal to half the product of its perimeter and apothem.

Let ACDEF be a regular polygon, whose centre is O and whose apothem is OP.

Draw the radii OA, OC, OD, OE, and OF; these will divide the polygon into equal triangles whose bases are the sides of the polygon and whose altitudes are each equal to the apothem (P. 2).

Now the area of any one of these triangles, as ACO, is equal to half the product of the side AC and the apothem OP; hence, the sum of the areas of the triangles, which is the area of the polygon, is equal to the sum of the sides, or the perimeter, multiplied by half the apothem, *which was to be proved.*

PROPOSITION V. THEOREM.

The circumference is the common limit of the perimeters of both the inscribed and the circumscribed regular polygons when the number of their sides is indefinitely increased by the method of continued duplication.

Let AC be a side of any regular polygon inscribed in the circle OA , and let DE be the corresponding side of the circumscribed polygon. Let OA and OF be the radius and apothem of the first polygon, and let OD and OG be the radius and apothem of the second polygon.

1°. In the triangle OAF , we have the relation,

$$OA - OF < AF,$$

that is, the difference between the radius and the apothem of the polygon is less than half of the side. If we now suppose the number of sides of the polygons to be indefinitely increased by the method of continued duplication, the value of AC will *decrease*, that of OF will *increase*, and the difference of OA and OF will *diminish*; finally when AC becomes less than any assignable quantity, OA and OF will become equal, and the perimeter will coincide with the circumference, *which was to be proved*.

2°. Because OD and OG are proportional to OA and OF , OD will become equal to OG when OA becomes equal to OF , and the perimeter of the circumscribed polygon will then coincide with the circumference OA , *which was to be proved*.

Cor. 1. When the perimeters of the circumscribed and inscribed polygons coincide with the circumference OA , their areas are equal to that of the circle OA .

Cor. 2. The area of a circle is equal to half the product of its circumference and radius.

Scho. A circle may be regarded as a regular polygon, having an infinite number of sides.

PROPOSITION VI. THEOREM.

The perimeters of two regular polygons having the same number of sides are to each other as their apothems, and their areas are to each other as the squares of their apothems.

Let ACDEF and PQRST be two regular polygons having the same number of sides, and let OK and ML be their apothems.

Draw the radii OA, OC, MP, and MQ.

The isosceles triangles ACO and PQM are similar to each other, because they are corresponding triangles of similar polygons (P. 12, *Cor.* 1, B. 4); their altitudes are therefore homologous lines of those polygons. Hence, the perimeters of the polygons are to each other as their apothems, and their areas are to each other as the squares of their apothems (P. 1, *Cor.*), *which was to be proved.*

Cor. 1. The circumferences of two circles are to each other as their radii, or as their diameters, and their areas are to each other as the squares of their radii, or as the squares of their diameters.

Cor. 2. Because similar sectors and similar segments are like parts of the circles to which they belong, their arcs are to each other as their radii, and their areas are to each other as the squares of their radii.

PROPOSITION VII. PROBLEM.

To inscribe a square in a circle; also to circumscribe a square about that circle.

Let ACDE be the given circle.

1°. Draw two diameters, AD and CE, perpendicular to each other; they will divide the circumference into four equal arcs. Draw the corresponding chords AC, CD, DE, and EA; they will form an inscribed square (P. 3).

2°. Draw tangents to the circumference at the points A, C, D, and E; they will form a circumscribed square, (P. 3, Cor. 2).

Scho. Having an inscribed and a circumscribed square, we may, by the method of continued duplication, construct regular inscribed and circumscribed polygons having 8, 16, 32, &c., sides.

PROPOSITION VIII. THEOREM.

The side of a regular inscribed hexagon is equal to the radius.

Let ACDEFG be a regular hexagon inscribed in the circle OA.

Draw the radii OA and OC.

The angle COA being an angle at the centre is equal to 4 right angles, *divided by 6*, that is, to $\frac{2}{3}$ of a right angle; hence, the sum of the angles ACO and OAC is equal to $\frac{1}{3}$ of a right angle, (P. 24, Cor. 1, B. 1); but ACO and OAC are equal because they lie opposite the equal sides OA and OC; hence, each is $\frac{1}{6}$ of a right angle. The triangle ACO is therefore equiangular and consequently equilateral, (P. 13, Cor., B. 1); hence, the side AC is equal to the radius OA, *which was to be proved.*

Cor. 1. If the radius of a circle is applied to the circum-

ference six times, as a chord, the resulting polygon will be a regular inscribed hexagon.

Cor. 2. If the alternate vertices A, D, and F, are joined by chords they will form a regular inscribed triangle.

Scho. By the method of continued duplication we may construct regular inscribed polygons of 12, 24, 48, &c., sides.

PROPOSITION IX. THEOREM.

The side of a regular inscribed decagon is equal to the greater segment obtained by dividing the radius in extreme and mean ratio.

Let AC be any side of a regular decagon inscribed in the circle OA.

Draw OA and OC; also draw AP bisecting OAC.

The angle COA being at the centre of a regular decagon is equal to 4 right angles *divided by 10*, that is, to $\frac{2}{5}$ of a right angle; hence, each of the angles ACO and OAC is equal to $\frac{1}{5}$ of a right angle, and consequently, each of the angles OAP and PAC is equal to $\frac{1}{10}$ of a right angle. The triangle OAP is therefore isosceles, and consequently the side AP is equal to OP. Now, the triangles ACO and CPA have the angle C in common, and the angles COA and PAC equal; they are therefore similar: hence, the triangle CPA is isosceles, the side AC being equal to AP, and consequently to OP. Because ACO and CPA are similar, we have,

$$CO : CA :: CA : CP,$$

or,

$$CO : OP :: OP : CP;$$

hence, OC is divided in extreme and mean ratio at P , (*Prob.* 5, *Scho.*, B. 3), and AC is equal to the greater segment, *which was to be proved*.

Cor. 1. If the radius of a circle is divided in extreme and mean ratio, and the greater segment applied ten times to the circumference as a chord, the resulting polygon will be a regular inscribed decagon.

Cor. 2. If the alternate vertices of the decagon are joined by chords, they will form a regular inscribed pentagon.

Scho. By the method of continued duplication, we may construct regular inscribed polygons of 20, 40, 80, &c., sides.

PROPOSITION X. PROBLEM.

The perimeters of a regular inscribed polygon and of a similar circumscribed polygon being given, to find the perimeters of regular inscribed and circumscribed polygons having double the number of sides.

Let AC be any side of the given inscribed polygon and DE the corresponding side of a similar circumscribed polygon, O the common centre of the polygons, and H the middle of the arc AHC .

Draw AH , and at A and C draw the tangents AL and CM ; then will AH be one side of the required inscribed polygon, and LM one side of the required circumscribed polygon.

Denote the perimeters of the given inscribed and circumscribed polygons, by p and P , and the perimeters of the required inscribed and circumscribed polygons by p' and P' .

but, AG and AH are like parts of p and p' ; hence,

$$AG : AH :: p : p'; \quad (8)$$

from (6), (7) and (8), we have,

$$p' : P' :: p : p',$$

or,

$$p' = \sqrt{p \times P'} \quad (b)$$

Scho. From formula (a) we can find the value of P' , and then from formula (b) we can find the value of p' .

PROPOSITION XI. PROBLEM.

To find the numerical value of a circumference whose diameter is equal to 1.

Let ACDE be a square inscribed in a circle OA, whose diameter AD is equal to 1; and let PQRS be a circumscribed square.

From P. 8, *Cor.* 2, B. 4, we have,

$$DE = DO\sqrt{2}, \quad \text{or} \quad DE = \frac{1}{2}\sqrt{2};$$

we also have each side of the circumscribed square equal to 1; hence, if we denote the perimeter of the inscribed square by p and that of the circumscribed square by P , we shall have

$$p = 2\sqrt{2} = 2.828427, \quad \text{and} \quad P = 4.$$

Substituting these values in formulas (a) and (b) of the preceding proposition and reducing, we find

$$P' = 3.313709, \quad \text{and} \quad p' = 3.061468,$$

in which p' and P' are the perimeters of regular inscribed and circumscribed octagons. Denoting these in turn by p and P

and substituting in formulas (a) and (b) and reducing, we have

$$P' = 3.182598 \quad \text{and} \quad p' = 3.121445,$$

in which p' and P' are the perimeters of regular inscribed and circumscribed polygons of 16 sides. By continuing this process of continued substitution and reduction, we can find in succession the perimeters of regular inscribed and circumscribed polygons of 32, 64, 128, &c., sides. If the operation is carried on till we come to the polygons of 2048 sides, we shall find

$$P' = 3.141592 \quad \text{and} \quad p' = 3.141588.$$

Now, these values of P' and p' differ from each other by less than a *hundredth thousandth* part of 1, and because the first is greater and the second less than the circumference, either of them differs from the circumference by less than they differ from each other. Hence, 3.14159 is an approximate value of the circumference, true to within less than the unit of the fifth decimal place. This number is usually denoted by the Greek letter π (called *pi*). By continuing the process above indicated the value of π may be found to any degree of accuracy. For most purposes of computation, it will be sufficiently accurate to assume

$$\pi = 3.1416.$$

Cor. 1. Because the circumferences of any two circles are to each other as their diameters, π is the numerical measure of the ratio of the diameter of any circle to its circumference.

Cor. 2. If we denote the circumference of a circle whose radius is r by c , we shall have

$$1 : \pi :: 2r : c, \quad \text{or} \quad c = 2\pi r,$$

that is, *the circumference is equal to its radius multiplied by 2π .*

Cor. 3. If we denote the area of a circle whose radius is r by a , we shall have, (P. 5, *Cor. 2*),

$$a = 2\pi r \times \frac{1}{2}r = \pi r^2,$$

that is, *the area of a circle is equal to the square of its radius multiplied by π .*

Cor. 4. The arc of a sector whose radius is r , and whose angle at the centre is n° , is equal to

$$2\pi r \times \frac{n^\circ}{360^\circ}, \text{ or to } \frac{\pi r n}{180}.$$

Cor. 5. The area of a sector whose radius is r and whose angle at the centre is n° , is equal to

$$\pi r^2 \times \frac{n^\circ}{360^\circ}, \text{ or to } \frac{\pi r^2 n}{360}.$$

BOOK VI.

PLANES AND ANGLES FORMED BY PLANES.

Definitions.

88. A **plane**, as already defined, is a surface such that a straight line through any two of its points lies wholly in the surface.

A plane is supposed to extend to an infinite distance in all directions ; its position is indicated by two or more of its lines.

89. A line is **perpendicular** to a plane, when it is perpendicular to all the lines of the plane that pass through its foot ; that is, through the point in which it meets the plane.

Conversely, the plane is then perpendicular to the line.

90. Two planes are **parallel** when they cannot meet, how far soever both may be extended.

91. A line is **parallel** to a plane, when it cannot meet the plane, how far soever both may be extended.

Conversely, the plane is then parallel to the line.

A line that is neither perpendicular, nor parallel, to a plane is said to be oblique to it.

PROPOSITION I. THEOREM.

One plane, and only one, can be passed through three points not in the same straight line.

Let A, C, and D be three points not in the same straight line.

Draw a line through A and C.

Now, it is obvious that a plane can be passed through AC. If we suppose the plane to be revolved about AC, as an axis, it will ultimately reach the point D, and in this position it will pass through A, C, and D; but if it is further revolved about AC in either direction it will no longer contain D. Hence, one plane, and only one, can be passed through A, C, and D, *which was to be proved*.

Cor. 1. Three points not in a straight line determine, that is, fix the position of a plane.

Cor. 2. A straight line and a point not in that line determine the position of a plane.

Cor. 3. Two lines, AC and AD, that intersect, determine the position of a plane. For, a plane through one line and any point of the other will contain both lines and will be fixed in position.

Cor. 4. Two parallel lines determine the position of a plane. For by definition the two lines are in the same plane, and because this plane passes through one of the lines and a point in the other it is fixed in position.

PROPOSITION II. THEOREM.

If two planes intersect, their intersection is a straight line.

Let the planes KL and PQ intersect, and let A and C be two points of their intersection.

Draw the straight line AC.

From the definition of a plane, AC must lie wholly in both planes; furthermore no point outside of AC can lie in both, otherwise we

should have two planes through a line and a point without it, which is impossible. Hence, the intersection is a straight line, *which was to be proved*.

Cor. A single straight line does not determine a plane.

PROPOSITION III. THEOREM.

If a straight line is perpendicular to each of two intersecting lines at their point of intersection, it is perpendicular to the plane of those lines.

Let AQ and DQ be two lines in the plane KL , and let PQ be perpendicular to both; then is it perpendicular to the plane KL .

Draw any line, QC , through Q in the plane KL , and through any point C of this line, draw AD , cutting AQ and DQ at A and D ; also draw PA , PC , and PD . Prolong PQ beyond KL , till QR is equal to PQ , and draw RA , RC , and RD .

Because AQ is perpendicular to PR at its middle point, AR is equal to AP (P. 16, B. 1), and for like reason DR is equal to DP ; hence, the triangle ARD is equal to APD , and consequently CR is equal to CP . The line CQ has, therefore, two of its points, Q and C , equally distant from P and R ; hence, PR is perpendicular to CQ . But, CQ is any line of KL passing through Q ; hence, PQ is perpendicular to the plane KL , *which was to be proved*.

Cor. 1. Only one perpendicular can be drawn to a plane at a given point. For, if there could be two, as PQ and SQ , a plane could be passed through them cutting the given plane in a line, QT , and we should then have two

perpendiculars to this line at the same point, which is impossible, (P. 2, B. 1).

Cor. 2. Only one perpendicular can be drawn to a plane from a point without. For, if two could be drawn, as PQ and PS, we should have two perpendiculars to QS from the same point P, which is impossible, (P. 5, B. 1).

PROPOSITION IV. THEOREM.

If from a point without a plane a perpendicular is drawn to the plane, and also oblique lines meeting the plane at different points :

1°. *Any two oblique lines that meet the plane at equal distances from the foot of the perpendicular are equal ;*

2°. *Of two oblique lines that meet the plane at unequal distances from the foot of the perpendicular, that which meets it at the greater distance is the greater ;*

3°. *The perpendicular is less than any oblique line.*

Let P be any point without the plane KL. Let PQ be perpendicular to KL ; let PA and PC be oblique lines meeting KL at equal distances from Q ; and let PA and PE be oblique lines meeting KL at unequal distances from Q.

1°. The lines PA and PC are equal. For, draw QA and QC : the right-angled triangles PQA and PQC have the side PQ common, and QA equal to QC ; they are therefore equal in all their parts ; hence, PA and PC are equal, *which was to be proved.*

2°. Draw QE and suppose it greater than QA ; then is PE greater than PA . For, lay off QD equal to QA , and draw PD ; then is PD equal to PA from what has just been proved. But, PE is greater than PD , (P. 15, B. 1); hence, PE is greater than PA , *which was to be proved.*

3°. The line PQ is less than any oblique line, as PA . For, in the triangle PQA , the angle A is less than the angle Q ; hence, PQ is less than PA , *which was to be proved.*

Cor. 1. All the equal oblique lines that can be drawn from P to KL , meet that plane in a circumference whose centre is Q . Hence, to draw a line perpendicular to a given plane from a point without, find three points of the plane equally distant from the given point and then find the centre of a circumference passing through them; the line from the given point to this centre is the required perpendicular.

Cor. 2. The angle QEP is the inclination of PE to the plane KL . All equal lines from P to KL are equally inclined to that plane; and of two unequal lines, the less line has the greater inclination.

PROPOSITION V. THEOREM.

If from the foot of a perpendicular to a plane, a line is drawn perpendicular to any line of the plane, and if the point of intersection is joined with any point of the perpendicular, the last line is perpendicular to the line of the plane.

Let PQ be perpendicular to the plane KL , and let QD be

drawn from Q perpendicular to AC, a line of KL, and let D be joined with any point P on PQ; then is PD perpendicular to AC.

Lay off from D, equal distances DA and DC; draw QA, QC, and PA, PC.

Because QD is perpendicular to AC, and DA equal to DC, QA is equal to QC. Now, the right-angled triangles PQA and PQC, have PQ common, and QA equal to QC; they are therefore equal in all their parts, and consequently PA is equal to PC. Because P and D are each equally distant from A and C, PD is perpendicular to AC, *which was to be proved*.

Cor. 1. AC is perpendicular to the plane of PD and QD, (P. 3).

Cor. 2. The shortest distance from PQ to AC, is QD; for QD is shorter than any other line, PC, that can be drawn from PQ to AC.

Scho. The lines PQ and AC are said to be perpendicular to each other, though they do not intersect. The angle between any two lines in space is equal to an angle formed by drawing lines through any point respectively parallel to the given lines.

PROPOSITION VI. THEOREM.

If one of two parallel lines is perpendicular to a plane, the other one is also perpendicular to that plane.

Let PQ and RS be parallel, and let PQ be perpendicular to the plane KL; then is RS perpendicular to KL.

Let QS be the intersection of the plane of the parallels with KL. Draw AC in the plane KL perpendicular to QS at S; also draw SP.

The line AC is perpendicular to the plane of PS and QS, and consequently to the plane of PQ and RS, (P. 5, Cor. 1); hence, ASR is a right angle. Because PQ is perpendicular to the plane KL, PQS is a right angle; and because PQ and RS are parallel, QSR is also a right angle, (P. 21, Cor. 2, B. 1). Hence, RS is perpendicular to SA and SQ at S, and consequently to their plane KL, *which was to be proved*.

Cor. 1. If a plane KL is perpendicular to each of two lines, PQ and RS, the lines are parallel. For, if not, a line could be drawn through Q parallel to RS, and this would be perpendicular to the plane KL and we should then have two lines through Q perpendicular to KL, which is impossible.

Cor. 2. If two lines, A and C, are parallel to a third line, D, not in their plane, they are parallel to each other. For if a plane is passed perpendicular to D it will also be perpendicular to both A and C.

PROPOSITION VII. THEOREM.

If a line lying without a plane is parallel to a line of the plane, it is parallel to that plane.

Let AC be parallel to the line DE of the plane KL; then is AC parallel to KL.

For, if AC could meet KL it would do so at some point of DE, because AC and DE are in the plane AE; but AC and DE cannot meet because they are parallel; hence, AC cannot meet the plane KL; it is therefore parallel to it, *which was to be proved*.

Cor. A plane through one of two parallels is parallel to the other.

PROPOSITION VIII. THEOREM.

If two planes are perpendicular to the same line they are parallel to each other.

Let the planes KL and MN be perpendicular to PQ at Q and P; then are they parallel to each other.

For if the planes could meet at any point, the lines from that point to P and Q would both be perpendicular to PQ; but, this is impossible, (P. 5, B. 1); hence, the planes cannot meet; they are therefore parallel to each other, *which was to be proved*.

Cor. If the points P and Q coincide, the planes KL and MN also coincide; hence, only one plane can be perpendicular to the same line at the same point.

PROPOSITION IX. THEOREM.

If a plane intersect two parallel planes the lines of intersection are parallel.

Let the plane CD intersect the parallel planes KL and MN in AC and DE; then are AC and DE parallel.

For, if they are not parallel they will meet, inasmuch as they lie in the plane CD, and if they meet, the planes KL and MN will meet; but, this is impossible; hence, AC and DE are parallel, *which was to be proved*.

PROPOSITION X. THEOREM.

If a line is perpendicular to one of two parallel planes it is also perpendicular to the other.

Let KL and MN be two parallel planes and let PQ be perpendicular to KL ; then will it be perpendicular to MN .

Pass a plane through PQ intersecting KL in QC and MN in PA . Now PQC is a right angle, and because QC and PA are parallel, (P. 9), QPA is also a right angle. Pass a second plane through PQ , intersecting KL in QE and MN in PD ; for the same reason as before, QPD is a right angle. Hence, PQ is perpendicular to both PD and PA at P ; it is therefore perpendicular to their plane MN , *which was to be proved*.

Cor. PQ is the shortest distance from P to KL .

PROPOSITION XI. THEOREM.

Parallel lines included between parallel planes are equal.

Let AC and DE be parallel lines between the parallel planes KL and MN ; then are they equal.

Draw AD and CE ; these are the intersections of the plane AE with the planes KL and MN ; they are therefore parallel; hence, $ACED$ is a parallelogram; its opposite sides are therefore equal, (P. 26, B. 1); consequently AC and DE are equal, *which was to be proved*.

Cor. 1. If AC and DE are perpendicular to KL they are also perpendicular to MN , and because they are equal, it follows that parallel planes are everywhere equally distant.

Cor. 2. If lines are drawn from any two points of CE perpendicular to the plane KL they are equal; hence, a line that is parallel to a plane is everywhere equally distant from that plane.

PROPOSITION XII. THEOREM.

If the sides of two angles, not in the same plane, are parallel and lie in the same direction, the angles are equal, and their planes are parallel.

Let PA and PD be respectively parallel to QC and QE, and let them lie in the same direction; then is the angle EQC equal to DPA, and their planes, KL and MN, are parallel.

1°. Draw any line, AD cutting PA and PD at A and D; lay off QC equal to PA, QE equal to PD, and draw CE; also draw AC, DE, and PQ.

Because PA and QC are parallel and equal, APQC is a parallelogram, and consequently AC is parallel and equal to PQ; for a like reason, DE is also parallel and equal to PQ. Now, because AC and DE are parallel and equal to PQ, they are parallel and equal to each other; hence, AD and CE are parallel and equal. The sides of the triangle APD are therefore respectively equal to the sides of CQE; hence, these triangles are equal in all their parts; consequently, the angles EQC and DPA are equal, *which was to be proved*.

2°. The planes KL and MN are parallel. For if they are not, let a plane be passed through A parallel to KL and suppose it to cut one of the lines, as PQ, in some other point than P, say R; AR will then be parallel to CQ (P. 9), and we shall have two lines through A parallel to CQ, which is impossible. Hence, the plane MN is parallel to KL, *which was to be proved*.

Cor. 1. If three lines, AC, DE, and PQ, not in the same plane, are equal and parallel, the triangles APD and CQE,

formed by joining their extremities are equal, and their planes are parallel.

Cor. 2. If two intersecting planes, PC and PE, are cut by two parallel planes, KL and MN, the angles APD and CQE formed by their intersections are equal.

PROPOSITION XIII. THEOREM.

If two lines are cut by three parallel planes, they are divided proportionally.

Let the lines AC and DE be cut by the parallel planes KL, MN, and PQ, the first at A, H, and C, and the second at D, F, and E; then is,

$$AH : HC :: DF : FE.$$

Draw DC, and let it pierce the plane MN at G. Draw AD, HG, GF, and CE.

The lines AD and HG are parallel, (P. 9); hence,

$$AH : HC :: DG : GC; \dots \dots \dots (1)$$

the lines GF and CE are also parallel; hence,

$$DF : FE :: DG : GC; \dots \dots \dots (2)$$

from (1) and (2), we have,

$$AH : HC :: DF : FE,$$

which was to be proved.

Cor. 1. If two lines are cut by any number of parallel planes, they are divided proportionally.

Cor. 2. If any number of lines are cut by any number of planes, they are divided proportionally.

Definitions.

92. A **diedral angle** is the inclination of two planes that meet. The planes are called **faces** of the angle, and the line in which they meet is called the **edge of the angle**.

A diedral angle is the same as a plane angle formed by two lines, one in each plane, and both perpendicular to the edge at the same point. Thus, if AC and DC are perpendicular to ML at C , the diedral angle of the planes LK and MN is equal to ACD . If this is a right angle, the planes are perpendicular to each other.

If two planes intersect, they form four diedral angles, equal two and two. These angles are called by the same names, and bear to each other the same relations, as the corresponding plane angles.

93. A **polyedral angle** is the angular space included within three or more planes meeting at a common point.

The planes are called **faces** of the polyedral angle, the lines in which the faces meet are called **edges**, and the point at which the edges meet is the **vertex**. The angle between two consecutive edges is called a **lateral angle**, and the angle between two consecutive faces is called an **interfacial angle**.

94. A **triedral angle** is a polyedral angle having three faces.

In the triedral angle whose vertex is O , the edges are OA , OC , and OD ; the lateral angles are AOC , COD , and DOA ; and the interfacial angles are the angles between the planes AOC , COD ; COD , DOA ; and DOA , AOC .

PROPOSITION XIV. THEOREM.

If a line is perpendicular to a plane, every plane through the line is perpendicular to that plane.

Let PQ be perpendicular to the plane KL , and let MN be any plane through PQ ; then is MN perpendicular to KL .

Draw QD in KL perpendicular to AM , the line in which MN intersects KL .

Because PQ is perpendicular to the plane KL it is perpendicular to both AM and QD . But, PQ is in the plane MN , and QD is in the plane KL , and both are perpendicular to AM at Q ; hence, the planes MN and KL are perpendicular to each other, (*Art. 92*), which was to be proved.

Cor. 1. Because QD is perpendicular to both QA and QP , it is perpendicular to their plane MN , that is, if two planes are perpendicular to each other, a line in one plane perpendicular to their intersection is perpendicular to the other plane.

Cor. 2. If three lines QD , QA , and QP , are perpendicular to each other at a common point, each is perpendicular to the plane of the other two.

Cor. 3. If two planes are perpendicular to a third plane, their intersection is perpendicular to that plane.

PROPOSITION XV. THEOREM.

The sum of any two lateral angles of a triedral angle is greater than the third lateral angle.

Let $\angle AOC$, $\angle COD$, and $\angle DOA$ be the lateral angles of the trihedral angle O ; then is the sum of any two, as $\angle AOC$ and $\angle COD$, greater than the third, $\angle DOA$.

If $\angle DOA$ is less than, or equal to, either of the other lateral angles, the proposition needs no proof; let us then suppose $\angle DOA$ is greater than either of the others.

Draw any line AD , cutting OA and OD at A and D ; then construct the angle $\angle AOE$ equal to $\angle AOC$; also lay off OC equal to OE and draw AC and CD .

The triangles $\triangle AOE$ and $\triangle AOC$ have two sides and their included angle equal, each to each; they are therefore equal in all their parts; consequently AE is equal to AC .

In the triangle $\triangle ACD$ we have

$$AC + CD > AD;$$

subtracting AC from the first member and its equal AE from the second member of this inequality, we have

$$CD > DE.$$

The triangles $\triangle COD$ and $\triangle DOE$ have DO common, CO equal to EO , and CD greater than DE ; hence, (P. 9, B. 1),

$$\angle COD > \angle DOE;$$

adding $\angle AOC$ to the first member of this inequality and its equal $\angle AOE$ to the second member, we have

$$\angle AOC + \angle COD > \angle DOE + \angle AOE, \text{ or } \angle AOD,$$

which was to be proved.

PROPOSITION XVI. THEOREM.

The sum of the lateral angles of a polyedral angle is less than four right angles.

Let AOC , COD , DOE , and EOA be the lateral angles of a polyedral angle O ; then is their sum less than four right angles.

Pass a plane cutting from the polyedral angle a polygon $ACDE$, and from a point within this polygon, as Q , draw lines to the vertices A , C , D , and E ; these will divide the polygon into as many basal triangles as the polyedral angle has faces, and the sum of all the angles of the basal triangles will be equal to the sum of all the angles of the lateral triangles AOC , COD , DOE , and EOA . If we consider the triedral angle A , we have $OAE + OAC$ greater than $QAE + QAC$ (P. 15); in like manner we have at the triedral angle C , $OCA + OCD$ greater than $QCA + QCD$; and so on for the other triedral angles. Hence, the sum of all the angles at the bases of the *lateral triangles* is greater than the sum of all the angles at the bases of the *basal triangles*; consequently the sum of all the angles at O is less than the sum of all the angles at Q . But, the sum of the angles at O is the sum of the lateral angles of the given polyedral angle, and the sum of the angles at Q is equal to four right angles; hence, the sum of the lateral angles of the polyedral angle is less than four right angles, *which was to be proved*.

Scho. The polyedral angle is supposed to be convex; that is, the faces are so arranged that any plane section of the angle is a convex, or salient, polygon.

PROPOSITION XVII. THEOREM.

If the lateral angles of two triedral angles are equal, each to each, the corresponding interfacial angles are also equal, each to each.

Let O and Q be two triedral angles in which the lateral angle

$\angle AOC$ is equal to $\angle EQF$, $\angle COD$ to $\angle FQG$, and $\angle DOA$ to $\angle GQE$; then are the corresponding interfacial angles equal.

Take any point A , on OA , and from it draw AC and AD , the former in the plane AOC , the latter in AOD , and both perpendicular to OA ; lay off QE equal to OA and from E draw EF and EG , the former in the plane EQF , the latter in EQG , and both perpendicular to QE ; also draw CD and FG . The angle $\angle DAC$ is the interfacial angle whose edge is OA , and $\angle GEF$ is the interfacial angle whose edge is QE .

In the right-angled triangle, OAC and QEF , OA is equal to QE , and the angle $\angle COA$ to $\angle FQE$; hence, these triangles are equal in all their parts; consequently AC is equal to EF , and OC to QF . In like manner it may be shown that AD is equal to EG , and OD to QG . Again, the triangles COD and FQG have two sides and their included angle equal, each to each; hence, these triangles are equal in all their parts; consequently, CD is equal to FG . Now, the triangles ACD and EFG have their sides equal, each to each; hence, the triangles are equal in all their parts; consequently, the angles $\angle DAC$ and $\angle GEF$ are equal, that is, the interfacial angles whose edges are OA and QE are equal. In like manner it may be shown that the interfacial angles whose edges are OC and QF are equal; also, that the interfacial angles whose edges are OD and QG are equal. Hence, the corresponding interfacial angles of the two trihedral angles are equal, *which was to be proved*.

Scho. In the case considered, the faces of the trihedral angles are similarly placed, and the trihedral angles may be so placed as to coincide throughout. If the faces are not similarly placed, as shown in the diagram, the angles cannot be made to coincide throughout: in

this case they are said to be **symmetrical**. Two triedral angles of this kind can be so placed that the lateral angles COD and FQG will coincide, the edge OA falling on one side and the edge QE on the other side of the common face. When so placed, for every point of OA on one side of the common plane there will be a corresponding point of QE on the other side, so situated that the line joining them is perpendicular to, and bisected by, that plane. The plane is then called a **plane of symmetry**.

Definition.

95. Any two magnitudes are **symmetrical** with respect to a plane, when they are so related that for every point of one there is a corresponding point of the other, such that the line joining them is perpendicular to, and bisected by, the plane.

The student may acquire a rough idea of what is meant by symmetry if he will place his hands together, palm to palm. The hands when so placed fulfil the requirements of symmetry.

BOOK VII.

COMPARISON AND MEASURE OF POLYEDRONS.

Definitions.

96. A **polyedron** is a volume bounded by plane surfaces.

The polygons determined by the intersection of these planes are called **faces**; the lines in which the faces meet are called **edges**; and the points in which the edges meet are called **vertices**.

97. A **prism** is a polyedron, two of whose faces are parallel and equal polygons, the remaining faces being parallelograms; as ACDEF-P.

The parallel polygons are called **bases**: that on which the prism is supposed to stand is called the **lower base**, or simply the **base**; the other is called the **upper base**. The remaining faces are called **lateral faces**, and taken together they make up the **lateral surface**; the lines in which the lateral faces meet are called **lateral edges**.

98. The **altitude** of a prism is the perpendicular distance between its bases.

99. A **right prism** is a prism whose lateral edges are perpendicular to the planes of its bases: in this case the altitude is equal to any lateral edge.

Prisms are said to be *triangular*, *quadrangular*, *pentagonal*, &c., according to the number of sides of their bases.

100. A **right section** of a prism is a section made by a plane perpendicular to its lateral edges.

101. A **parallelopipedon** is a prism whose bases are parallelograms.

102. A **rectangular parallelopipedon** is a parallelopipedon whose bases and lateral faces are all rectangles; as AR.

A **cube** is a rectangular parallelopipedon whose faces are equal squares.

103. A **pyramid** is a polyedron, one of whose faces is any polygon, the others being triangles having a common vertex; as ACDE-V.

The polygon is the **base**, and the triangles are **lateral faces**. The lateral faces taken together make up the **lateral surface**; the lines in which the lateral faces meet are **lateral edges**; and the point at which the lateral edges meet is the **vertex**.

104. The **altitude** of a pyramid is the perpendicular distance from its vertex to the plane of its base; as VP.

105. A **right pyramid** is one whose base is a regular polygon, the line from the centre of this polygon to the vertex being perpendicular to the base.

It is obvious from P. 4. B. 6, that the lateral edges of a right pyramid are all equal; it is also plain that the lateral faces are all equal.

106. The **slant height** of a right pyramid is the altitude of any lateral face ; as VK.

107. A **frustum of a pyramid** is that part of a pyramid included between the base and a secant plane parallel to the base.

The intersection of the secant plane with the pyramid is called the **upper base** of the frustum, and the distance between the upper and the lower base is the **altitude**. If the frustum is part of a right pyramid its **slant height** is the altitude of any lateral face.

108. Two polyhedrons are **similar** when their faces are similar and similarly placed.

109. A **diagonal of a polyhedron** is a line joining any two vertices not in the same plane.

PROPOSITION I. THEOREM.

A secant plane parallel to the base of a prism divides the lateral edges and the altitude proportionally, and the section which it cuts from the prism is equal to the base.

Let ACDE-P be a prism whose altitude is PM; let HL be a section made by a plane parallel to the base; and let N be the point in which this plane cuts PM.

1°. Because the planes CE, HL, and QS are parallel, they divide the lines AP, CQ, DR, ES, and MP proportionally (P. 13, Cor. 2, B. 6), *which was to be proved.*

2°. Because the planes CE and HL are parallel, the angles of GHKL are equal to the corresponding angles of ACDE, (P. 12, Cor. 2, B. 6), and because the corresponding sides of

GHKL and ACDE are parallels included between parallels, the polygons are equal to each other; hence, the section HL is equal to the base CE, *which was to be proved*.

Cor. 1. If MN is equal to NP, AG is equal to GP, and the two segments of the prism are equal. For let the upper segment be placed on the lower one so that the section HL shall coincide with the base CE; then, because the lateral angles of the triedral angles G and A are equal, each to each, and similarly placed, GP will fall on AG, and P will coincide with G; for like reason Q will coincide with H, R with K, and S with L; hence, the segments will coincide throughout.

Cor. 2. If any number of planes are passed parallel to the base so as to divide MP into equal parts, they will also divide the prism into equal segments.

PROPOSITION II. THEOREM.

A secant plane parallel to the base of a pyramid divides the lateral edges and the altitude proportionally, and the section which it cuts from the pyramid is similar to the base.

Let ACDE-V be a pyramid whose altitude is VM; let QS be a section made by a plane parallel to the base, and let N be the point in which this plane cuts VM. Also let KL be a plane through V parallel to the base.

1°. Because the planes CE, QS, and KL are parallel, they divide the lines AV, CV, DV, EV, and MV proportionally, *which was to be proved*.

2°. Because the planes CE and QS are parallel, the angles

of the section QS are equal to the corresponding angles of the base. Again, because PQ is parallel to AC,

$$PQ : AC :: QV : CV, \quad (1)$$

and in like manner,

$$QR : CD :: QV : CV; \quad (2)$$

from (1) and (2), we have,

$$PQ : AC :: QR : CD.$$

In like manner it may be shown that the remaining sides of the section QS are proportional to the corresponding sides of the base CE. Hence, the section is similar to the base, *which was to be proved.*

Cor. 1. The section QS, is to the base CE, as the square of the distance of the section from the vertex, is to the square of the altitude of the pyramid. For, the section being similar to the base, we have, (P. 12, *Cor.* 2, B. 4),

$$PQRS : ACDE :: \overline{PQ}^2 : \overline{AC}^2. \quad (3)$$

But, $PQ : AC :: QV : CV :: NV : MV,$

or, $\overline{PQ}^2 : \overline{AC}^2 :: \overline{NV}^2 : \overline{MV}^2; \quad (4)$

from (3) and (4), we have,

$$PQRS : ACDE :: \overline{NV}^2 : \overline{MV}^2.$$

Cor. 2. If two pyramids having equal bases lying in the same plane, and equal altitudes, are cut by a plane parallel to the bases, the sections are equal.

PROPOSITION III. THEOREM.

The area of the lateral surface of a right prism is equal to the perimeter of its base multiplied by its altitude.

Let $ACDEF-P$ be a right prism; then are all its lateral faces rectangles, whose bases are the sides of $ACDEF$, and whose altitudes are equal to the altitude of the prism.

The area of any lateral face, as AQ , is equal to its base, AC , multiplied by its altitude, AP ; hence, the sum of the areas of all the lateral faces is equal to the sum of the sides of $ACDEF$, multiplied by the altitude of the prism AP , *which was to be proved.*

PROPOSITION IV. THEOREM.

The area of the lateral surface of a right pyramid is equal to the perimeter of its base multiplied by half its slant height.

Let $ACDE-V$ be a right pyramid whose slant height is VK ; then are all its lateral faces equal isosceles triangles, whose bases are the sides of $ACDE$, and whose altitudes are equal to VK .

The area of any lateral face, as AEV , is equal to its base AE , multiplied by half its altitude KV ; hence, the sum of the areas of all the lateral faces is equal to the sum of the sides of the base, multiplied by half the slant height, VK , *which was to be proved.*

Cor. The lateral surface of a frustum of a right pyramid is equal to half the sum of the perimeters of its bases, multiplied by its slant height. For any lateral face, as AQ , (see figure, P. 2), is equal to half the sum of its sides, AC and PQ , multiplied by the slant height; hence, the lateral surface is equal to half the sum of the perimeters of $ACDE$ and $PQRS$, multiplied by the slant height.

PROPOSITION V. THEOREM.

The volume of any triangular prism is equal to that of a right prism, whose base is a right section of the given prism, and whose altitude is equal to the lateral edge of that prism.

Let $ACD-PQR$ be any triangular prism, and let EFG be one of its right sections. Prolong the lateral edges, making AK equal to PE , CL to QF , and DM to RG ; draw KL , LM , and MK ; then will EK be equal to PA , FL to QC , and GM to RD , and each will be equal to a lateral edge of the prism.

Because EK and FL are parallel and equal, EF is parallel and equal to KL ; for like reason, FG is parallel and equal to LM , and GE to MK ; hence, $KLM-E$ is a right prism whose base is equal to EFG and whose altitude is equal to AP . Furthermore, the polyedron $KLM-ACD$ is equal to the polyedron $EFG-PQR$, because all the parts of the one are equal to the corresponding parts of the other and are similarly placed. Now, if we take the first of these, from the polyedron $KLM-PQR$, there will remain the prism $ACD-P$, and if we take the second from the same polyedron, there will remain the prism $KLM-E$; hence, these prisms are equal, *which was to be proved.*

PROPOSITION VI. THEOREM.

The opposite lateral faces of a parallelepipedon are equal, each to each.

Let $ACDE-P$ be a parallelepipedon whose bases are AD and PR ; these bases are equal and parallel polygons by definition, and the lateral faces are parallelograms.

Because CA is equal and parallel to DE , and CQ to DR , the faces CP and DS are equal and parallel; in like manner it may be shown that the faces CR and AS are equal and parallel, *which was to be proved*.

Cor. Any two opposite faces of a parallelopipedon may be taken as its bases.

PROPOSITION VII. THEOREM.

If two triangular prisms have the faces that include a triedral angle in one equal to the faces that include a triedral angle in the other, each to each, and if these faces are similarly placed, the prisms are equal.

Let $ACD-P$ and $EFG-K$ be two triangular prisms having the face EFG equal to ACD , the face EL to AQ , and the face FM to CR .

Because the lateral angles about F are equal to those about C , and because they are similarly placed, the triedral angle F is equal to the triedral angle C , (P. 17, *Scho.*, B. 6). Let the prism $EFG-K$ be placed on $ACD-P$ so that the triedral angles F and C shall coincide; then will L fall on Q , M on R , and K on P , and consequently, the prisms will coincide throughout; they are therefore equal, *which was to be proved*.

Cor. If two right triangular prisms have equal bases and equal altitudes they are equal.

PROPOSITION VIII. THEOREM.

If a plane is passed through the diagonally opposite edges of a parallelopipedon, it divides the parallelopipedon into two equal triangular prisms.

Let $ACDE-P$ be a parallelopipedon, AR a plane through AP and DR , and let $FGHK$ be one of its right sections; then are FGH and HKF right sections of the prisms $ACD-P$ and $DEA-P$.

The side FG is parallel and equal to KH , the side GH is parallel and equal to FK , and the side HF is common; hence, the triangles FGH and HKF are equal. Now, the triangular prism $ACD-P$ is equal to a right prism whose base is FGH and whose altitude is AP , and the triangular prism $DEA-P$ is equal to a right prism whose base is HKF and whose altitude is AP . But, right prisms whose bases are FGH and HKF , and whose altitudes are AP , are equal (P. 7, Cor.); hence, the prisms $ACD-P$ and $DEA-P$ are equal, *which was to be proved.*

PROPOSITION IX. THEOREM.

Two rectangular parallelopipedons having equal bases, are to each other as their altitudes.

Let $ACDE-K$ and $PQRS-T$ be two rectangular parallelopipedons whose equal bases AD and PR lie in the same plane PD .

1°. Let their altitudes AK and PT be to each other as two whole numbers, say as 3 is to 5.

Divide AK into 3, and PT into 5 equal parts, and through the points of division pass planes parallel to the plane PD ; these will divide the first parallelopipedon into 3 segments and the second prism into 5 segments, all equal to each other, (P. 1, Cor. 2); hence,

$$ACDE-K : PQRS-T :: 3 : 5; \quad . . . \quad (1)$$

but, $AK : PT :: 3 : 5; \quad \quad (2)$

hence, from (1) and (2), we have

$$ACDE-K : PQRS-T :: AK : PT,$$

which was to be proved.

2°. Let the altitudes AK and PT be incommensurable. Let AK be divided into m equal parts, and let one of these be applied to PT and suppose that it is contained in it n times with a remainder less than that part; then will

$$\frac{PT}{AK} = \frac{n}{m} \text{ to within less than } \frac{1}{m}; \quad . . . \quad (3)$$

through the points of division of AK and PT pass planes parallel to PD ; these planes will divide $ACDE-K$ into m equal segments, and $PQRS-T$ into n segments, each equal to those of $ACDE-K$, with a remainder less than one of these segments; hence,

$$\frac{PQRS-T}{ACDE-K} = \frac{n}{m} \text{ to within less than } \frac{1}{m} \quad . . \quad (4)$$

Because m is any whole number, the ratios expressed by the first members of (4) and (3) are equal; hence,

$$ACDE-K : PQRS-T :: AK : PT,$$

which was to be proved.

PROPOSITION X. THEOREM.

Two rectangular parallelopipeds, having equal altitudes, are to each other as their bases.

Let the rectangular parallelopipeds ACDE-K and PEQR-S have equal altitudes and let them be placed as shown in the diagram.

Prolong the plane CK till it meets the face RW in the line LF.

The parallelopipeds AM and AW have the same base AN; they are therefore to each other as their altitudes, that is,

$$ACDE-K : LAEQ-F :: ED : EQ ; . . (1)$$

the parallelopipeds AW and PW have the same base EW; they are therefore to each other as their altitudes, that is,

$$LAEQ-F : RPEQ-S :: EA : EP ; . . (2)$$

multiplying (1) by (2), term by term, and dividing the first couplet of the resulting proportion by LAEQ-F, we have,

$$ACDE-K : RPEQ-S :: ED \times EA : EQ \times EP.$$

But, $ED \times EA$ is equal to the base of the first parallelopipedon and $EQ \times EP$ is equal to the base of the second parallelopipedon; hence, these parallelopipedons are to each other as their bases, *which was to be proved.*

Definitions and Explanations.

110. The unit of volume is a cube, each of whose edges is equal to the linear unit.

111. The measure of a volume is the number of times it contains the assumed unit.

If two volumes have the same measure, they are said to be equal; if they are capable of superposition, they are said to be equal in all their parts.

The product of three lines is the product of the numbers that express the lengths of the lines. The product of a surface by a line is the product of the number of superficial units in the surface by the number of linear units in the line. In either case, the unit of the product is the unit of volume.

The *length*, the *breadth*, and the *height*, of a magnitude are called its *dimensions*.

PROPOSITION XI. THEOREM.

The volume of a rectangular parallelepipedon is equal to the product of its base and altitude, that is, to the product of its three dimensions.

Let FN be a rectangular parallelepipedon and let AR be a cube, each of whose edges is a linear unit, and let them be placed as shown in the diagram.

Extend the faces AQ, CR, and DS till they meet the plane of the upper base of FN.

Now, the parallelepipedons FN and AW have the same altitude HN; they are therefore proportional to their bases; hence,

$$FGHK-L : ACDH-T :: FGHK : ACDH. \dots (1)$$

Again, the parallelepipedons AW and AR have the same base AD; they are therefore to each other as their altitudes; hence,

$$ACDH-T : ACDH-P :: HN : HS; \dots (2)$$

multiplying proportions (1) and (2), term by term, and dividing both terms of the first couplet of the resulting proportion by $ACDH \cdot T$, we have,

$$FGHK-L : ACDH-P :: FGHK \times HN : ACDH \times HS,$$

or, passing to numerical values,

$$FGHK-L : 1 :: FGHK \times HN : 1,$$

whence, $FGHK-L = FGHK \times HN = HG \times HK \times HN$,

which was to be proved.

PROPOSITION XII. THEOREM.

If two parallelopipedons have the same lower base, and if their upper bases lie between the same parallels, they are equal.

Let the parallelopipedons $ACDE-K$ and $ACDE-P$, have the same lower base and let their upper bases lie between the parallels QK and RN .

Now the base KM may fall entirely without the base PR , or it may partially coincide with that base; in either case, PK will be equal to QL , and SN to RM .

The triangular prisms $KAP-S$ and $LCQ-R$, have the face KAP equal to LCQ , the face $AESP$ to $CDRQ$, and the face $KPSN$ to $LQRM$; they are therefore equal, (P. 7). Now if we take the first of these prisms from the polyedron $ACDE-KQRN$, there will remain the parallelepipedon $ACDE-P$, and we take the second prism from the same polyedron, there will remain the parallelepipedon $ACDE-K$; hence, the two parallelepipedons are equal, *which was to be proved.*

PROPOSITION XIII. THEOREM.

The volume of any parallelepipedon is equal to that of a right prism having the same base and the same altitude.

Let ACDE-K be any parallelepipedon and let ACDE-P be a right prism having the same base and the same altitude; then will their upper bases lie in the same plane.

Prolong QR, PS, KL, and NM till, by their intersection, they form the parallelogram WXYZ; this parallelogram will be equal and parallel to the base ACDE.

Now, conceive a parallelepipedon to be formed whose lower base is ACDE and whose upper base is WXYZ. This parallelepipedon is equal to ACDE-P and also to ACDE-K, (P. 12); hence, ACDE-K is equal to ACDE-P, *which was to be proved.*

Cor. 1. The right prism ACDE-P is equal to a rectangular parallelepipedon having the same dimensions. For, through AP and CQ pass planes perpendicular to the face ER; these planes will determine a rectangular parallelepipedon ACFO-P, having the same dimensions as the prism ACDE-P, and equal to it (P. 12).

Cor. 2. The volume of any parallelepipedon is equal to that of a rectangular parallelepipedon having the same dimensions.

Cor. 3. The volume of any parallelepipedon is equal to

the product of its base and altitude, or to the product of its three dimensions.

Cor. 4. Any two parallelopipedons are to each other as the products of their three dimensions. If they have one dimension in common they are to each other as the products of the other two. If they have two dimensions in common they are to each other as their remaining dimensions.

Cor. 5. The volume of any triangular prism is equal to the product of its base and altitude (P. 8).

PROPOSITION XIV. THEOREM.

The volume of any prism is equal to the product of its base and altitude.

Let ACDEF-P be any prism. Through any lateral edge, as CQ, pass planes CT and CS, dividing the prism into triangular prisms; these will all have the same altitude as the given prism.

Now, each triangular prism is equal to the product of its base and altitude; hence, their sum is equal to the sum of their bases multiplied by their common altitude, that is, the volume of the given prism is equal to the product of its base and altitude, *which was to be proved.*

Cor. 1. Any two prisms are to each other as the products of their bases and altitudes.

Cor. 2. Two similar prisms are to each other as the cubes of their homologous edges. For, their bases are to each other as the squares of any two homologous edges, and their altitudes are to each other as those edges; hence, the prisms are to each other as the cubes of any two homologous edges.

PROPOSITION XV. THEOREM.

Triangular pyramids having equal bases and equal altitudes are equal.

Let $ACD-V$ and $acd-v$ be triangular pyramids having their bases equal and lying in the same plane; and let CZ be their common altitude; then, if the pyramids are not equal let the first, $ACD-V$, be the greater.

Divide CZ in m equal parts and through the points of division let planes be passed parallel to ACD ; then will each of these planes intersect the two pyramids in equal triangles, (P 2, Cor. 2). On ACD , EFG , &c., as bases, construct exterior prisms having their lateral edges parallel and equal to CF , FH , &c.; also on the triangles cfg , mhn , &c., as bases construct interior prisms having their lateral edges parallel and equal to cf , fh , &c. Now the sum of the exterior prisms is greater than the first pyramid, and the sum of the interior prisms is less than the second pyramid; hence, the difference between these sums is greater than the difference between the pyramids. But, the second external prism is equal to the first internal prism, because they have equal bases and equal altitudes; the third external prism is equal to the second internal prism; and so on: hence, the difference between the sum of the external and the sum of the internal prisms is equal to the first external prism. Consequently, the difference between the pyramids is less than that prism, that is, less than a prism whose base is ACD

and whose altitude is one of the equal parts of CZ . But m is any number; if we suppose it increase indefinitely and finally to become greater than any assignable number, each part of CZ will become less than any assignable number, and the prism $ACD-F$ will also become less than any assignable quantity, that is, the difference between the pyramids will be less than any assignable quantity; they are therefore equal to each other, *which was to be proved*.

PROPOSITION XVI. THEOREM.

Any triangular prism can be divided into three equal triangular pyramids.

Let $ACD-P$ be any triangular prism. Pass a plane through D , C , and P ; also pass a plane through D , Q , and P ; these planes divide the given prism into three pyramids $ACD-P$, $CDQ-P$, and $RQD-P$.

The pyramids $CDQ-P$ and $RDQ-P$ have their bases equal because they are halves of the parallelogram $DCQR$, and their altitudes equal because their bases are in the same plane and their vertices at the same point; hence, they are equal (P. 15). But the pyramid $RQD-P$ may be considered as having the base PQR and the vertex D . Now the pyramids $PQR-D$ and $ACD-P$ are equal, because they have equal bases, PQR and ACD , and equal altitudes each being equal to the altitude of the given prism. Hence, the three pyramids into which the prism is divided are equal, *which was to be proved*.

Cor. 1. A triangular pyramid is one-third of a prism having the same base and the same altitude.

Cor. 2. The volume of any triangular pyramid is equal to one-third the product of its base and altitude.

PROPOSITION XVII. THEOREM.

The volume of any pyramid is equal to one-third the product of its base and altitude.

Let ACDEF-V be any pyramid. Through any lateral edge, as CV, pass planes, CVE and CVE, dividing it into triangular pyramids; these will have the same altitude as the given pyramid. Now, each triangular pyramid is equal to one-third the product of its base and altitude; hence, their sum is equal to the sum of their bases multiplied by one-third their common altitude, that is, the volume of the given pyramid is equal to one-third the product of its base and altitude, *which was to be proved.*

Cor. 1. Any two pyramids are to each other as the product of their bases and altitudes.

Cor. 2. Two similar pyramids are to each other as the cubes of their homologous edges. For, their bases are to each other as the squares of any two homologous edges, and their altitudes are to each other as those edges; hence, the pyramids are to each other as the cubes of any two homologous edges.

PROPOSITION XVIII. THEOREM.

A frustum of a triangular pyramid is equal to the sum of three pyramids whose common altitude is the altitude of the frustum and whose bases are the lower base of the frustum, the upper base of the frustum, and a mean proportional between these bases.

Let ACD - PQR be a frustum of a triangular pyramid.

First, pass a plane through D , C , and P ; it will cut off a pyramid whose base is the lower base of the frustum, and whose altitude is that of the frustum. Then, pass a plane through D , P , and Q ; it will cut off a pyramid whose base is the upper base of the frustum, and whose altitude is that of the frustum, and there will remain the pyramid whose base is DQC and whose vertex is P .

Draw PS parallel to QC ; also draw SD and SQ ; PS will be parallel to the plane DQC , (P. 7, B. 6), and the points S and P will be equally distant from that plane, (P. 11, Cor. 2, B. 6); hence, the pyramids DQC - P and DQC - S have the same base and the same altitude; they are therefore equal. But the last named pyramid may be regarded as having the base SCD , and the vertex Q . If we draw ST parallel to AD , or PR , the triangle SCT will be equal to PQR , and SCD will be a mean proportional between ACD , and SCT , or PQR , (P. 11, Cor. 2, B. 4); hence, the pyramid SCD - Q has for its base, a mean proportional between the two bases of the frustum, and for its altitude, the altitude of the frustum. The frustum is therefore equal to three pyramids whose common altitude is that of the frustum, and whose bases are the lower base of the frustum, the upper base of the frustum, and a mean proportional between these bases, *which was to be proved*.

Cor. 1. The volume of a triangular frustum is equal to the sum of its bases *plus* a mean proportional between them, multiplied by one-third of its altitude.

Cor. 2. The volume of a frustum of any pyramid is equal to the sum of its bases, *plus* a mean proportional between them, multiplied by one-third of its altitude. For, the

planes that divide the entire pyramid into triangular pyramids will divide the frustum into triangular frustums having the same altitude as the given frustum. Now, if a plane parallel to the base cuts the given frustum in a section which is a mean proportional between its bases, it will cut each triangular frustum in a section which is a mean proportional between its bases; that is, the sum of the mean proportionals of the bases of the several triangular frustums is a mean proportional between the bases of the given frustum. The volume of the given frustum is the sum of the volumes of the triangular frustums; hence, it is equal to the sum of their upper bases *plus* the sum of their lower bases *plus* the sum of the mean proportionals of their bases multiplied by one-third their common altitude; that is, the volume of any frustum is equal to the sum of its bases *plus* a mean proportional between them, multiplied by one-third of its altitude.

General Scholium. Let the volume of a right prism be denoted by V , its lateral surface by L , the area of its base by B , the perimeter of its base by P , and its altitude by A ; then from P. 3 and P. 14 we have,

$$L = PA, \quad \dots \dots \dots (a)$$

$$V = BA, \quad \dots \dots \dots (b)$$

Let the volume of a right pyramid be denoted by V , its lateral surface by L , the area of its base by B , the perimeter of its base by P , its altitude by A , and its slant height by S ; then from P. 4 and P. 17, we have,

$$L = \frac{1}{2}PS, \quad \dots \dots \dots (c)$$

$$V = \frac{1}{3}BA. \quad \dots \dots \dots (d)$$

Let the volume of a right pyramidal frustum be denoted by V , its lateral surface by L , the areas of its bases by B and b , the corresponding perimeters by P and p , its altitude by A , and its slant height by S ; then from P. 4, *Cor.*, and P. 18, *Cor.*, we have,

$$L = \frac{1}{2}S(P + p), \quad \dots \dots \dots (e)$$

$$V = \frac{1}{3}A(B + b + \sqrt{Bb}). \quad \dots \dots \dots (f)$$

BOOK VIII.

MEASURE OF THE CYLINDER, CONE, AND SPHERE.

Definitions.

112. A **cylinder** is a volume that may be generated by a rectangle revolving about one of its sides.

If the rectangle AD is revolved about the side AE it will generate a cylinder. The side AE is the **axis**; the surface generated by CD is the **lateral surface**; any position of CD is an **element** of the lateral surface; the circles generated by AC and ED are **bases**; and the distance between the bases is the **altitude**.

Any line of the rectangle, as PQ , parallel to AC , will generate a circle equal and parallel to the base; hence, every section parallel to the base is a circle. Any section through the axis is a rectangle double the generating rectangle.

In Elementary Geometry the term *cylinder* is used in a restricted sense; whereas in the Higher Geometry it is applied to any volume bounded in part by plane surfaces and in part by a curved surface whose elements are parallel straight lines. The term *cone*, in Elementary Geometry, is used in a similarly restricted sense.

113. An **inscribed prism** is one whose bases are inscribed in those of the cylinder; as ACDEFG-P. Its edges are elements of the lateral surface, and if the bases are regular polygons the line, KL, joining their centres, is the **axis** of the prism.

114. A **cone** is a volume that may be generated by a right-angled triangle revolving about a side adjacent to the right angle.

If the triangle ACV, right-angled at A, is revolved about AV, it will generate a cone. The side AV is the **axis**; the surface generated by CV is the **lateral surface**; any position of CV is an **element** of the lateral surface; the circle generated by AC is the **base**; the distance, VA, from the vertex to the base is the **altitude**; and the distance, VC, from the vertex to the circumference of the base is the **slant height**. Any line of the triangle, as PQ, parallel to AC, will generate a circle parallel to the base; hence, every section parallel to the base is a circle. Any section through the axis is an isosceles triangle, double the generating triangle.

115. An **inscribed pyramid** is one whose vertex is the vertex of the cone and whose base is inscribed in that of the cone; as ACDEFG-V. Its edges are elements of the lateral surface, and if its base is a regular polygon the line from its centre to the vertex is the **axis** of the pyramid.

116. A **frustum of a cone**, or a **conic frustum**, is that

part of a cone included between the base and a section parallel to the base.

If the bi-rectangular trapezoid $LKCQ$ is revolved about the side LK , adjacent to the two right angles, it will generate a conic frustum, whose bases are the circles KC and LQ , whose altitude is LK , and whose slant height is QC .

117. An inscribed frustum of a pyramid is one whose bases are inscribed in those of the conic frustum; as $ACDEFG-P$. If its bases are regular polygons, the line joining their centres is the axis of the conic frustum.

118. Similar cylinders are those that may be generated by the revolution of similar rectangles, and similar cones are those that may be generated by the revolution of similar triangles about homologous sides.

PROPOSITION I. THEOREM.

The limit of an inscribed prism, whose base is a regular polygon, is the circumscribing cylinder.

Let $ACDEFG-P$ be an inscribed prism, whose base is a regular polygon.

If the number of sides of the base is increased by the method of continued duplication, the base of the prism will approach that of the cylinder; when the number of sides becomes infinite the two bases will coincide, and the prism will coincide with the cylinder; hence, the circumscribing cylinder is the limit of the inscribed prism, *which was to be proved.*

Cor. 1. A cylinder is a right prism, whose base is a regular

polygon having an infinite number of sides. Hence, whatever is true of the prism is true of the cylinder, (Art. 66).

Cor. 2. The lateral surface of a cylinder is equal to the circumference of its base multiplied by its altitude, (P. 3, B. 7).

Cor. 3. The volume of a cylinder is equal to the product of its base and altitude, (P. 14, B. 7). Hence, any two cylinders are to each other as the products of their bases and altitudes.

Cor. 4. Similar cylinders are to each other as the cubes of their altitudes, or as the cube of any two homologous lines, (P. 14, *Cor. 2*, B. 7).

PROPOSITION II. THEOREM.

The limit of an inscribed pyramid, whose base is a regular polygon, is the circumscribing cone.

Let ACDEFG-V be an inscribed pyramid whose base is a regular polygon.

If the number of sides of the base is increased by the method of continued duplication, the base of the pyramid will approach that of the cone; when the number of sides becomes infinite, the two bases will coincide, and the pyramid will coincide with the cone; hence, the circumscribing cone is the limit of the inscribed pyramid, *which was to be proved.*

Cor. 1. A cone is a right pyramid, whose base is a regular polygon having an infinite number of sides.

Cor. 2. A secant plane parallel to the base of a cone divides its slant height and its altitude proportionally, (P. 2, B. 7).

Cor. 3. Any two sections of a cone parallel to its base are to each other as the squares of their distances from the vertex, (P. 2, *Cor. 1*, B. 7).

Cor. 4. The lateral surface of a cone is equal to the circumference of its base multiplied by half its slant height, (P. 4, B. 7).

Cor. 5. The volume of a cone is equal to one-third the product of its base and altitude, (P. 17, B. 7).

Cor. 6. Similar cones are to each other as the cubes of their altitudes, or as the cubes of any two homologous lines, (P. 17, *Cor. 2*, B. 7).

PROPOSITION III. THEOREM.

The limit of an inscribed frustum of a pyramid, whose bases are regular polygons, is the circumscribing conic frustum.

Let ACDEFG-P be an inscribed frustum whose bases are regular polygons. If the number of sides of each base is increased by the method of continued duplication, the bases of the pyramidal frustum will approach those of the conic frustum; when the number of sides becomes infinite the bases of the two frustums will coincide, and the pyramidal frustum will coincide with the conic frustum; hence, the circumscribing conic frustum is the limit of the inscribed pyramidal frustum, *which was to be proved.*

Cor. 1. A frustum of a cone is a frustum of a right pyramid, whose bases are regular polygons having an infinite number of sides.

Cor. 2. The lateral surface of a conic frustum is equal to

half the sum of the circumferences of its bases multiplied by its slant height, (P. 4, *Cor.*, B. 7).

Cor. 3. The volume of a conic frustum is equal to the sum of its bases *plus* a mean proportional between the bases, multiplied by one-third of the altitude, (P. 18, *Cor.* 2, B. 7).

PROPOSITION IV. THEOREM.

If a straight line is revolved about an axis wholly exterior to it, the surface generated is equal to the revolving line, into the circumference generated by its middle point.

Let AC be any line, PQ an axis exterior to it, and let G be the middle point of AC.

Through A, G, and C, draw AE, GF, and ND, perpendicular to PQ, and through G draw MN parallel to PQ. The right-angled triangles AMG and CNG, have the hypotenuse AG equal to GC, and the angle AGM to CGN; they are therefore equal in all their parts; hence, MA is equal to CN, that is, FG is as much less than EA as it is greater than DC; the line FG is therefore equal to half the sum of EA and DC, and consequently the circumference FG is equal to half the sum of the circumference EA and DC.

If AC is revolved about PQ it generates the lateral surface of a conic frustum whose slant height is AC and whose bases are the circumferences EA and DC; but this surface is equal to AC multiplied by half the sum of the circumferences EA and DC, that is, it is equal to AC, multiplied by the circumference FG, *which was to be proved.*

Scho. The proposition holds true when AC meets PQ at D, in which case AC generates the lateral surface of a cone; it also holds true when AC is parallel to PQ, in which case AC generates the lateral surface of a cylinder.

Definitions.

119. A sphere is a volume bounded by a surface all of whose points are equally distant from a point within, called the centre.

Any line from the centre to a point of the surface is a radius; any line through the centre and limited by the surface is a diameter. All radii of the same sphere are equal, and all diameters of the same sphere are equal.

A sphere may be generated by a semicircle revolving about its diameter, as an axis. In this revolution every point of the semi-circumference will generate the circumference of a circle whose plane is perpendicular to the axis, and whose radius is the distance of that point from the axis.

120. A plane is tangent to the surface of a sphere when it touches it in a single point. This point is called the point of contact.

121. A zone is a portion of the surface included between two parallel planes. The distance between the planes is the altitude of the zone, and the lines in which the planes cut the surface are the bases of the zone.

If one of the limiting planes is tangent to the surface, the zone has but one base.

122. A spherical segment is a portion of a sphere included between two parallel planes. The distance between the planes is the altitude of the segment, and the sections which the planes cut from the sphere are the bases of the segment.

If one of the limiting planes is tangent to the surface of the sphere, the segment has but one base.

123. A spherical sector is a volume that may be gener-

ated by any sector of a semicircle when the semicircle is revolved about its diameter.

The spherical sector is usually bounded by a zone and two conic surfaces; if the axis coincides with one of the extreme radii of the circular sector, the spherical sector is bounded by a zone and one conical surface. One of the conic surfaces may reduce to a plane.

PROPOSITION V. THEOREM.

Any plane section of a sphere is a circle.

Let the sphere OQ be cut by any plane ACD ; let OQ be a radius of the sphere perpendicular to the plane ACD , and piercing it at P .

Let A , C , and D , be any three points of the intersection of the plane with the surface of the sphere, and draw OA , OC , and OD .

Because OA , OC , and OD are radii of the sphere they are equal; consequently the points A , C , and D , are in the circumference of a circle whose centre is P , (*P. 4, Cor., B. 6*). But A , C , and D , are any points in the line of intersection; hence, the intersection is a circle, *which was to be proved*.

Cor. 1. If the cutting plane passes through the centre of the sphere, the radius of the section is equal to the radius of the sphere; such a section is called a **great circle**. If the cutting plane does not pass through the centre of the sphere, the radius of the section is less than that of the sphere; such a section is called a **small circle**.

Cor. 2. The radius of the sphere that passes through the centre of a small circle is perpendicular to the plane of that circle; *conversely*, a line through the centre of a small circle, and perpendicular to its plane, passes through the centre of the sphere.

Cor. 3. The plane of a great circle bisects the sphere. For the two parts into which it divides the sphere may be placed so as to coincide; otherwise there would be points on the surface of the sphere unequally distant from its centre.

Cor. 4. One great circle can always be passed through any two points on the surface of a sphere, and but one. For, one plane can always be passed through the given points and the centre of the sphere, and but one; this plane cuts the sphere in a great circle.

If the points are at the extremities of a diameter, an infinite number of great circles can pass through them.

PROPOSITION VI. THEOREM.

If a plane is perpendicular to any radius of a sphere at its extremity, it is tangent to the surface of the sphere; conversely, if a plane is tangent to the surface of a sphere, it is perpendicular to the radius drawn to the point of contact.

1°. Let OP be any radius of the sphere, and let KL be a plane perpendicular to OP at P ; let OQ be a line drawn from O to any point of KL , except P .

Because OP is perpendicular, and OQ oblique to KL , OQ is greater than OP ; consequently, Q lies without the sphere; hence, every point of the plane KL , except P , lies without the sphere; consequently, KL is tangent to the surface at P , which was to be proved.

2°. Let the plane KL be tangent to the sphere at P , and let Q be any point of KL , except P .

Because KL is tangent to the surface at P , Q lies without the sphere, that is, OQ is greater than OP ; hence OP is the shortest line from O to KL ; it is therefore perpendicular to KL , which was to be proved.

Definitions.

124. If an arc is divided into any number of equal parts, the corresponding chords form a **regular broken line**. If the arc is a semi-circumference the broken line is a **regular semi-perimeter**, and the area included between it and the diameter is a **regular semi-polygon**. The parts of the broken line are called **sides**.

125. If lines are drawn from the extremities of any side perpendicular to the diameter, the part of the diameter intercepted between them is called the **projection** of the side. Thus KL and LM are projections of CD and DE .

PROPOSITION VII. THEOREM.

The surface of a sphere is equal to the circumference of a great circle multiplied by its diameter.

Let $ACDEFG$ be a regular semi-perimeter whose apothem is OP . Through P , the middle of EF , draw PQ perpendicular to AG ; draw EM and FN perpendicular to AG ; also, draw FR parallel to AG .

If the semi-perimeter is revolved about AG as an axis, any side as EF will generate the surface of a conic frustum whose measure is the circumference QP , into the slant height EF , (P. 4). But the triangles OPQ and EFR have their sides perpendicular,

each to each; they are therefore mutually equiangular and consequently similar; hence,

$$OP : QP :: EF : RF, \text{ or } MN;$$

whence, $QP \times EF = OP \times MN,$

or, $\text{circum } QP \times EF = \text{circum } OP \times MN,$

that is, the surface generated by any side is equal to a circumference whose radius is the apothem, multiplied by the projection of that side on the axis. Hence, the surface generated by the entire semi-perimeter is equal to the circumference whose radius is the apothem, multiplied by the sum of the projections of all its sides, that is, by AG.

If the number of sides of the semi-polygon is made infinite by the method of continued duplication, the semi-perimeter will become the semi-circumference whose diameter is AG, the apothem will become the radius of the semi-circumference, and the surface generated will become the surface of a sphere; hence, the surface of a sphere is equal to the circumference of a great circle multiplied by its diameter, *which was to be proved.*

Cor. 1. If we denote the radius of a sphere by R, the circumference of a great circle will be equal to $2\pi R$, (P., B. 5), and consequently, the surface of the sphere will be equal to $2\pi R \times 2R$, or to $4\pi R^2$, that is, to *four great circles.*

Cor. 2. The surfaces of any two spheres are to each other as the squares of their radii.

Cor. 3. The area of any zone is equal to the circumference of a great circle multiplied by its altitude. For, the generating arc may be regarded as a regular broken line, having an infinite number of sides, and whose projection is equal to the altitude of the zone.

Cor. 4. Any two zones of the same sphere are to each other as their altitudes.

Cor. 5. The lateral surface of a circumscribed cylinder is equal to the circumference of a great circle multiplied by the diameter of the sphere; it is therefore equal to the surface of the sphere. If we include the bases, the surface of a circumscribed cylinder is to the surface of the sphere as 6 is to 4, or as 3 is to 2.

PROPOSITION VIII. THEOREM.

The volume of a sphere is equal to its surface multiplied by one-third of its radius.

Let ACDEFGH be a regular semi-polygon whose centre is O, and let the radii OC, OD, &c., be drawn, dividing it into equal isosceles triangles; furthermore, let us suppose that the semi-polygon has an even number of sides, in which case every side is oblique to AH.

Draw OP perpendicular to GH, and OQ perpendicular to FG; draw FL and GM perpendicular to AH; and prolong FG till it meets AH at T.

If the regular semi-polygon is revolved about AT as an axis, it will generate a volume equal to the sum of the volumes generated by the triangles OHG, OGF, &c. Now, the volume generated by the triangle OGH is made up of two cones whose vertices are O, and H, and whose common base is the circle generated by MG; denoting this volume by the expression *vol* OGH, we have,

$$\text{vol OGH} = \pi \overline{MG}^2 \times \frac{1}{3} \overline{OH} = \frac{1}{3} \pi \overline{MG} \times \overline{MG} \times \overline{OH}. \dots (1)$$

But, $\overline{MG} \times \overline{OH} = \overline{GH} \times \overline{OP}$, because each is equal to twice the triangle OGH; hence,

$$vol\ OGH = \frac{1}{3}\pi\overline{MG} \times \overline{GH} \times \overline{OP}. \quad . \quad . \quad . \quad (2)$$

The surface generated by \overline{GH} is equal $2\pi\overline{MG} \times \frac{1}{3}\overline{GH}$, (P. 2, Cor. 4), or to $\pi\overline{MG} \times \overline{GH}$; denoting this surface by the expression *surf* GH, we have, from (2),

$$vol\ OGH = surf\ GH \times \frac{1}{3}OP. \quad . \quad . \quad . \quad (3)$$

Again, we have, in like manner,

$$vol\ OFT = surf\ FT \times \frac{1}{3}OQ, \quad . \quad . \quad . \quad (4)$$

and, $vol\ OGT = surf\ GT \times \frac{1}{3}OQ; \quad . \quad . \quad . \quad (5)$

subtracting (5) from (4), member from member, remembering that OQ is equal to OP, we have,

$$vol\ OFG = surf\ FG \times \frac{1}{3}OP.$$

In like manner it may be shown that the volume generated by any of the isosceles triangles is equal to the surface generated by its base, multiplied by one-third of the apothem. Hence, the volume generated by the semi-polygon is equal to the surface generated by the semi-perimeter, multiplied by one-third of the apothem.

If now we suppose the number of sides of the semi-polygon to be made infinite by the method of continued duplication, the semi-polygon will become a semicircle, its apothem will become the radius, and the volume generated will be the volume of a sphere; hence, the volume of a sphere is equal to its surface multiplied by one-third of its radius, *which was to be proved.*

Cor. 1. If we denote the radius of the sphere by R, its

BOOK IX.

SPHERICAL GEOMETRY.

Definitions.

126. A **spherical angle** is an angle on the surface of a sphere included between the arcs of two great circles.

The arcs are called **sides**, and the point at which they meet is called the **vertex** of the angle.

The angle between two curves meeting at a point is the same as the angle between the tangents to the curves at their common point.

127. A **spherical polygon** is a part of the surface of a sphere, bounded by arcs of three or more great circles.

The bounding arcs are **sides**, the points at which the sides meet are **vertices**, and the arcs of great circles joining two vertices not consecutive are **diagonals** of the polygon.

128. A **spherical triangle** is a spherical polygon of three sides.

Spherical triangles are classified in the same manner as plane triangles.

129. A **spherical pyramid** is a portion of a sphere bounded by a spherical polygon, and by sectors of circles whose arcs are the sides of the polygon.

The spherical polygon is the **base** of the pyramid, and the centre of the sphere is its **vertex**.

130. A **lune** is a portion of the surface of a sphere, bounded by semi-circumferences of two great circles.

The semi-circumferences are **sides**, and the angle between them is the **angle of the lune**. The volume bounded by the lune and by the planes of its sides is called a **spherical wedge**.

131. The **axis** of a circle is a line perpendicular to the plane of the circle through its centre.

132. The **poles** of any circle of a sphere are the points in which the axis of the circle meets the surface of the sphere.

In what follows each side of a spherical polygon is supposed to be less than a semi-circumference; the distance between any two points on the surface is supposed to be measured on the arc of a great circle passing through them; all the polygons treated of are supposed to be *salient* and to be situated on the same sphere or on equal spheres. Furthermore, all the arcs referred to are supposed to be arcs of great circles unless the contrary is indicated, either by words, or by the nature of the case.

PROPOSITION I. THEOREM.

Either pole of a circle is equally distant from every point of its circumference.

Let the circle OA be a circle of the sphere whose centre is C , and let PQ be its axis: this axis passes through C , and the points P and Q in which it pierces the surface are the poles of the circle OA . Let PAQ be a semicircle whose diameter is PQ .

If this semicircle is revolved about PQ , it will generate the sphere, and the point A will generate the circumference of the circle OA ; hence, the distance of every point of the circumference OA , from P , is the arc PA , and the dis-

tance of every point from Q is the arc QA, *which was to be proved.*

Cor. 1. The middle point, E, of the arc PEQ generates the circumference of a great circle CE; hence, every point in the circumference of a great circle is at a quadrant's distance from each of its poles.

Cor. 2. If two points of the surface of a sphere, not the extremities of a diameter, are each at a quadrant's distance from a third point, the latter point is the pole of a great circle passing through two former points.

Scho. The arc PA is called the spherical radius of the circle OA: when the pole of an arc and its spherical radius are known, the arc can be drawn on the surface of a sphere with the same facility that a circle can be drawn on a plane surface.

PROPOSITION II. THEOREM.

A spherical angle is measured by the arc of a great circle described from the vertex as a pole, and limited by the sides of the angle.

Let FAG be a spherical angle and let AD and AE be tangent to its sides at A; also, let FG be an arc of the great circle whose pole is A.

Draw the radii CF, CG, and CA.

Because DA and EA are tangent to FA and GA, at A, they are perpendicular to CA at that point; hence, the angle DAE is the measure of the diedral angle whose faces are FCA and GCA. Because FA and GA are quadrants, the radii FC and GC are perpendicular to the radius CA at C; hence, the angle FCG is also the measure of the diedral angle whose faces are FCA and GCA. The angle DAE is therefore equal to FCG; but, the angle FCG is measured by the arc FG; hence, DAE, or FAG, is measured by the arc FG, *which was to be proved.*

Cor. The arc FG measures the angle of the lune whose sides are PFA and PGA.

Scho. If arcs of two great circles intersect, as AC and DE, they form four angles about V; of these angles, the opposite ones are equal, and any two adjacent ones are supplementary.

PROPOSITION III. THEOREM.

Any side of a spherical triangle is less than the sum of the other two.

Let ACD be a spherical triangle, on a sphere whose centre is O.

Draw the radii OA, OC, and OD.

The planes AOC, COD, and DOA form a triedral angle O, whose lateral angles are measured by the sides of ACD; but any one of these angles is less than the sum of the other two, (P. 15, B. 6); hence, any side of ACD is less than the sum of the other two, *which was to be proved.*

Cor. The sum of the lateral angles of the polyedral angle O is less than 4 right angles, (P. 16, B. 6); hence, the sum of the sides of a spherical triangle is less than 4 quadrants.

PROPOSITION IV. THEOREM.

If the vertices of one spherical triangle are poles of the sides of a second spherical triangle, then are the vertices of the second triangle poles of the sides of the first triangle.

Let the vertices of the spherical triangle ACD be the poles of the sides of the spherical triangle EFG.

Draw the arcs DE and CE.

Because D is the pole of FE, the arc DE is a quadrant, and because C is the pole of EG, the arc CE is a quadrant; hence E is the pole of CD (P. 1, Cor. 2); in like manner it may be shown that F is the pole of DA, and G the pole of CA, *which was to be proved.*

Scho. 1. The triangles ACD and EFG are called polar triangles, each being the polar triangle of the other.

Scho. 2. If all the sides of EFG are prolonged they will determine a group of four triangles, a central one, C, and three lateral ones, L. In like manner if the sides of ACD are prolonged they will determine a similar group. The term *polar triangles* is applied only to the central ones of each group.

PROPOSITION V. THEOREM.

Any angle of a spherical triangle is the supplement of the side lying opposite to it in the polar triangle.

Let ACD be any spherical triangle, and let EFG be its polar triangle.

Prolong DA and DC till they meet EF, at H and K.

Because DH and DK are quadrants, HK is the measure of the angle D, (P. 2). Because E is the pole of DK, EK is a quadrant, and because F is the pole of DH, FH is a quadrant; consequently $EK + FH$, or $EF + HK$, is equal to a semi-circumference, that is, the arc HK is the supplement of FE; hence, D is the supplement of FE; in like manner it may be shown that A is the supplement of FG, and C the supplement of GE, *which was to be proved.*

Cor. Any side of either triangle is the supplement of the opposite angle of its polar triangle.

Definition.

133. Two spherical triangles are said to be **symmetrical** when all their parts are equal, each to each, but placed in a reverse order in the two triangles.

Thus, ACD and EFG are symmetrical if the side AC is equal to EF , CD to FG , DA to GE , and the angle A to E , C to F , D to G .

Symmetrical triangles correspond to symmetrical triedral angles at the centre, and also to symmetrical spherical pyramids whose vertices are at the centre.

PROPOSITION VI. PROBLEM.

To construct a spherical triangle that shall be symmetrical with respect to a given spherical triangle.

Let ACD be a spherical triangle lying on a sphere whose centre is O .

With D as a pole and DA as a spherical radius, describe an arc; with C as a pole and CA as a spherical radius, describe a second arc cutting the first at E . Draw the arcs EC and ED ; also draw the radii OA , OC , OD , and OE .

The side EC is equal to AC , ED is equal to AD , and DC is common; hence, the sides of ECD and ACD are equal each to each, but taken in a reverse order. The lateral angles EOC , EOD , and COD , are respectively equal to AOC , AOD , and COD ; hence the corresponding interfacial angles are

equal, (P. 17, B. 6), that is, the angle E is equal to A , the angle ECD to ACD , and the angle EDC to ADC ; hence, the angles of the triangles ECD and ACD are equal, each to each, but taken in a reverse order. The triangle ECD is therefore symmetrical with respect to ACD , *which was to be proved*.

Cor. If DA is equal to DC , DE is also equal to DC , and the symmetrical triangles are both isosceles. In this case if the triangle ECD is placed on CDA so that the angle EDC shall coincide with its equal CDA , the arc ED will coincide with CD , the arc CD with AD , and the two triangles will coincide throughout.

Scho. Symmetrical triangles cannot be made to coincide unless they are isosceles.

PROPOSITION VII. THEOREM.

If two spherical triangles have two sides and the included angle of one, equal to two sides and the included angle of the other, each to each, their remaining parts are equal, each to each.

Let FGH and ACD be two spherical triangles in which FG is equal to AC , GH to CD , and the angle FGH to ACD ; also, let ACD and ECD be symmetrical.

The triangle FGH can be placed on ACD , or else on its symmetrical triangle ECD so as to coincide with it, as may be shown by a course of reasoning similar to that employed in demonstrating P. 8, B. 1; hence, the side HF is equal to DA , the angle F to A , and the angle FHG to ADC , *which was to be proved*.

PROPOSITION VIII. THEOREM.

If two spherical triangles have two angles and the included side of one, equal to two angles and the included side of the other, each to each, their remaining parts are equal, each to each.

Let FGH and ACD be two spherical triangles, in which the angle FGH is equal to ACD , the angle FHG to ADC , and the side GH to CD ; also, let ECD be symmetrical with ACD .

The triangle FGH can be placed on ACD , or else on its symmetrical triangle, so that they will coincide throughout, as may be shown by a course of reasoning similar to that employed in demonstrating P. 10, B. 1; hence, the side FG is equal to AC , the side HF to DA , and the angle F to E , or to A , *which was to be proved*.

NOTE.—Let the student demonstrate this and the preceding theorem in detail, following the methods indicated.

PROPOSITION IX. THEOREM.

If two spherical triangles have their sides equal, each to each, their angles are equal, each to each.

Let FGH and ACD be two spherical triangles, in which FG is equal to AC , GH to CD , and HF to DA .

If radii are drawn from the vertices of each triangle to the centre of the sphere on which it lies, they will be the edges of two triedral angles whose lateral angles are equal, each to each; hence their interfacial angles are equal, each to each (P. 17, B. 6). But these are

the angles of the given triangles ; hence the angles of the given triangles are equal, each to each, *which was to be proved.*

Cor. If two spherical triangles have their angles equal, each to each, the sides of their polar triangles will be equal, each to each (P. 5), and consequently the sides of the given triangles are equal, each to each.

PROPOSITION X. THEOREM.

If two sides of a spherical triangle are equal, their opposite angles are equal ; conversely, if two angles are equal, their opposite sides are equal.

1°. Let ACD be a spherical triangle in which DA is equal to DC , and let DE be an arc drawn from D to the middle point of AC .

The triangles CED and AED have DE common, EC equal to EA , and CD to AD ; their angles are therefore equal, each to each, (P. 9) ; hence, the angle C is equal to A , *which was to be proved.*

2°. Let ACD be a triangle in which the angles C and A are equal, and let its polar triangle be denoted by P .

The sides of P , lying opposite C and A , are equal, (P. 5, *Cor.*) ; consequently, their opposite angles are equal from what has just been proved ; hence, the sides of the given triangle lying opposite to these angles are equal, *which was to be proved.*

Cor. 1. If all the sides of a spherical triangle are equal, all its angles are equal, and the reverse.

Cor. 2. The arc drawn from the vertex of an isosceles triangle to the middle of its base, is perpendicular to the base, and bisects the angle at the vertex.

PROPOSITION XI. THEOREM.

In any spherical triangle, the greater side lies opposite to the greater angle; and conversely, the greater angle lies opposite to the greater side.

1°. Let ACD be a spherical triangle, in which the angle D is greater than C .

Draw the arc DE , making the angle CDE equal to C ; then is DE equal to CE , (P. 10).

The sum DE and EA is greater than DA , (P. 3); but, $DE + EA$ is equal to $CE + EA$, or to CA ; hence, CA is greater than DA , *which was to be proved.*

2°. Let CA be greater than DA ; then is the angle D greater than C . For, if D is equal to C , we have CA equal to DA , or if D is less than C , CA is less than DA , both of which are contrary to the hypothesis; hence, D must be greater than C , *which was to be proved.*

PROPOSITION XII. THEOREM.

The sum of the angles of a spherical triangle is less than six right angles and greater than two right angles.

Let ACD be any spherical triangle, and let EFG be its polar triangle.

Because each angle of ACD is the supplement of the opposite side of EFG , the sum of the angles of ACD is equal to 6 right angles *minus* the sum of the sides of EFG ; hence, this sum is less than 6 right angles. Again, because the sum of the sides of EFG is less than 4 right angles, (P. 3, *Cor.*), the sum of the

angles of ACD is greater than 2 right angles, *which was to be proved.*

Cor. All the angles of a spherical triangle may be right angles, or all may be obtuse.

Scho. 1. If DA and DC are quadrants, A and C are right angles and the triangle is bi-rectangular.

Scho. 2. If in addition, AC is a quadrant, the angle D is a right angle and the triangle is tri-rectangular.

Scho. 3. If three planes are placed through the centre of a sphere, perpendicular to each other, they divide its surface into 8 equal parts, each of which is a *tri-rectangular triangle*. Hence, a tri-rectangular triangle is one-eighth of the surface of the sphere, or it is equal to one-half of a great circle. The same planes divide the sphere into 8 equal spherical pyramids, each of which is equal to $\frac{1}{8}$ of $\frac{4}{3}\pi R^3$, or to $\frac{1}{6}\pi R^3$, (Gen. Scho., B. 8). The volume of a tri-rectangular spherical pyramid is equal to the tri-rectangular triangle which forms its base multiplied by $\frac{1}{6}$ of the radius.

PROPOSITION XIII. THEOREM.

The area of a lune is to the surface of the sphere as the angle of the lune is to four right angles.

Let PAQ be a semicircumference whose centre is O, and whose diameter is PQ; and let PA be a quadrant.

If the semicircumference is revolved about PQ, as an axis, through an angle AOC it will generate a lune whose angle is APC, or AOC, and if it is revolved through four right angles it will generate the surface of the sphere. Now, it is obvious that the surface generated whilst revolving through any angle is proportional to that angle; hence, the surface of the lune, is to the surface of the sphere, as the angle of the lune, is to four right angles, *which was to be proved.*

Cor. 1. If we denote the area of the lune by L , its angle, in terms of a right angle as a unit, by A , the area of the tri-rectangular triangle by T , remembering that the surface of the sphere is equal to 8 tri-rectangular triangles, we shall have,

$$L : 8T :: A : 4,$$

whence, $L = 2A \times T$,

that is, the area of a lune is equal to twice the angle of the lune, multiplied by the area of the tri-rectangular triangle.

Cor. 2. Whilst the semi-circumference generates the lune the semicircle generates the corresponding wedge, and whilst the semi-circumference generates the surface of the sphere, the semicircle generates the volume of the sphere; hence, the volume of a spherical wedge, is to the volume of the sphere, as the angle of the wedge, is to four right angles.

PROPOSITION XIV. THEOREM.

The areas of two symmetrical spherical triangles are equal.

Let ACD and EFG be two symmetrical spherical triangles.

Through A , C , and D , pass a plane cutting the sphere in a small circle whose pole is P . Draw the arcs PA , PC , and PD ; these arcs will be equal (P. 1). From F as a pole, with CP as a spherical radius, describe an arc, and from G as a pole, with the same arc as a spherical radius, describe a second arc cutting the first at Q ; then draw the arcs QE , QF , and QG .

Because QF and QG are equal to PC and PD the triangles QFG and PCD are isosceles and symmetrical, (P. 6, *Cor.*); they are therefore equal in all their parts; hence, the angle FGQ is equal to CDP. Now, the points Q and P may both lie without the triangles EFG and ACD, or they may both lie within those triangles; in either case, the angle EGQ is equal to ADP, and consequently, all the parts of the triangle EGQ are equal to the corresponding parts of ADP, (P. 7); hence, QE is equal to PA; the triangles EGQ and ADP are therefore isosceles and equal, as are also the triangles EFQ and ACP.

If Q and P lie without the triangles EFG and ACD, EFG is equal to the sum of EGQ and EFQ, diminished by FGQ; and ACD is equal to the sum of ADP and ACP, diminished by CDP; if Q and P lie within EFG and ACD, EFG is equal to the sum of EFQ, EGQ, and FGQ; and ACD is equal to the sum of ACP, ADP, and CDP. Hence, in either case the areas of EFG and ACD are equal, *which was to be proved.*

PROPOSITION XV. THEOREM.

If the semi-circumferences of two great circles intersect on the surface of a hemisphere, the sum of the opposite triangles which they form is equal to a lune whose angle is equal to the angle formed by the semi-circumferences.

Let ADC and FDE be two semi-circumferences intersecting at D, on the surface of the hemisphere whose great circle is AFCE.

Prolong the arcs DA and DF till they meet at G, forming the lune GFDA.

Because EDF and DFG are semi-circumferences, ED is

equal to FG ; for like reason, CD is equal to AG ; and because CEA and EAF are semi-circumferences, CE is equal to AF ; hence, the triangles CED and AFG are mutually equilateral, and consequently, mutually equiangular, (P. 9); they are therefore symmetrical and equal in area. But the sum of the triangles FDA and AGF is equal to the lune whose angle is ADF ; hence, the sum of the triangles FDA and CDE is also equal to that lune, *which was to be proved*.

Definitions.

134. The spherical excess of a spherical triangle is equal to the excess of the sum of its angles above two right angles.

If the right angle is taken as a unit, and if the angles of the triangle are denoted by A , C , and D , and the spherical excess by E , we have

$$E = A + C + D - 2.$$

If the angles are expressed in degrees, the spherical excess is equal to the sum of the angles of the triangle *minus* 180° , divided by 90° . Thus, if $A = 85^\circ$, $B = 105^\circ$, and $C = 50^\circ$, we have

$$E = \frac{85^\circ + 105^\circ + 50^\circ - 180^\circ}{90^\circ} = \frac{60^\circ}{90^\circ} = \frac{2}{3}.$$

135. The spherical excess of a spherical polygon is equal to the excess of the sum of its angles over the product of two right angles by the number of sides of the polygon *less* two; for if the polygon is divided into triangles by diagonals drawn from any vertex, the spherical excess of the polygon is equal to the sum of the numbers expressing the spherical excess of each triangle.

PROPOSITION XVI. THEOREM.

The area of a spherical triangle is equal to its spherical excess, multiplied by the area of a tri-rectangular triangle.

Let ACD be a spherical triangle lying on the surface of a hemisphere whose great circle is EGL.

Prolong the sides of the triangle till they meet the circumference EGL. Denote the angles of the triangle, expressed in terms of a right angle, by A, D, and C, and denote the area of a tri-rectangular triangle by T.

By the preceding proposition, the sum of the triangles AHK and AEF is equal to a lune whose angle is A, that is, to $2A \times T$, (P. 15); in like manner, the sum of the triangles CLE and CGH is equal to $2C \times T$, and the sum of the triangles DGF and DLK is equal to $2D \times T$. But the sum of the six triangles named, is equal to the area of the hemisphere *plus* twice the area of the triangle ACD. Because the hemisphere is equal to $4T$, we have

$$2 \times \text{area ACD} = 2A \times T + 2C \times T + 2D \times T - 4T;$$

whence, by reducing and factoring,

$$\bullet \quad \text{area ACD} = (A + C + D - 2) T,$$

which was to be proved.

Cor. The area of a spherical polygon ACDEF is equal to its spherical excess, multiplied by the area of a tri-rectangular triangle. For if we divide the polygon into triangles by diagonals drawn from the vertex A, the area of the polygon will be equal to the sum of

Cor. Any side of either triangle is the supplement of the opposite angle of its polar triangle.

Definition.

133. Two spherical triangles are said to be **symmetrical** when all their parts are equal, each to each, but placed in a reverse order in the two triangles.

Thus, ACD and EFG are symmetrical if the side AC is equal to EF , CD to FG , DA to GE , and the angle A to E , C to F , D to G .

Symmetrical triangles correspond to symmetrical triedral angles at the centre, and also to symmetrical spherical pyramids whose vertices are at the centre.

PROPOSITION VI. PROBLEM.

To construct a spherical triangle that shall be symmetrical with respect to a given spherical triangle.

Let ACD be a spherical triangle lying on a sphere whose centre is O .

With D as a pole and DA as a spherical radius, describe an arc; with C as a pole and CA as a spherical radius, describe a second arc cutting the first at E . Draw the arcs EC and ED ; also draw the radii OA , OC , OD , and OE .

The side EC is equal to AC , ED is equal to AD , and DC is common; hence, the sides of ECD and ACD are equal each to each, but taken in a reverse order. The lateral angles EOC , EOD , and COD , are respectively equal to AOC , AOD , and COD ; hence the corresponding interfacial angles are

equal, (P. 17, B. 6), that is, the angle E is equal to A, the angle ECD to ACD, and the angle EDC to ADC; hence, the angles of the triangles ECD and ACD are equal, each to each, but taken in a reverse order. The triangle ECD is therefore symmetrical with respect to ACD, *which was to be proved*.

Cor. If DA is equal to DC, DE is also equal to DC, and the symmetrical triangles are both isosceles. In this case if the triangle ECD is placed on CDA so that the angle EDC shall coincide with its equal CDA, the arc ED will coincide with CD, the arc CD with AD, and the two triangles will coincide throughout.

Scho. Symmetrical triangles cannot be made to coincide unless they are isosceles.

PROPOSITION VII. THEOREM.

If two spherical triangles have two sides and the included angle of one, equal to two sides and the included angle of the other, each to each, their remaining parts are equal, each to each.

Let FGH and ACD be two spherical triangles in which FG is equal to AC, GH to CD, and the angle FGH to ACD; also, let ACD and ECD be symmetrical.

The triangle FGH can be placed on ACD, or else on its symmetrical triangle ECD so as to coincide with it, as may be shown by a course of reasoning similar to that employed in demonstrating P. 8, B. 1; hence, the side HF is equal to DA, the angle F to A, and the angle FHG to ADC, *which was to be proved*.

It will be shown that every conic section is a **parabola**, an **ellipse**, or an **hyperbola**.

I. THE PARABOLA.

Definitions.

3. A **parabola** is a plane curve that may be generated by a point, moving so that it shall always be equally distant from a fixed line and from a given point.

The fixed line is called the **directrix**; the given point is the **focus**, the line through the focus perpendicular to the directrix is the **axis**; and the point in which the axis meets the curve is the **vertex** of the parabola.

PROPOSITION I. PROBLEM.

To construct a parabola when its directrix and focus are given.

Let LD be the directrix, and F the focus. Through F , draw a line EH , perpendicular to ED ; it will be the axis.

Let KGD be a triangular ruler, right-angled at G . Take a string equal in length to KG ; fasten one end at K and the other at F ; then press a pencil against the string, keeping its point in contact with the ruler, and move the ruler so that the edge GD shall coincide with LD ; the pencil will trace out an arc of a parabola. For, in every position we shall have GP equal to FP .

Cor. 1. The point A , midway between E and F , is a point of the curve, and because it lies on EH , it is the vertex of the parabola.

Cor. 2. The curve is symmetrical with respect to EH. For, draw PH perpendicular to EH and prolong it till it meets the curve at Q; join F with Q, and draw QL perpendicular to LD. Because LQ and GP are parallels between parallels, they are equal; but LQ is equal to FQ and GP to FP, from the definition of the curve; hence, FQ, and FP are equal to each other, and consequently HQ and HP are equal, (P. 15, *Cor. 1*, B. 1), that is, for every point on one side of EH there is a corresponding symmetrical point on the other side.

PROPOSITION II. THEOREM.

If a point lies without a parabola, its distance from the directrix is less than its distance from the focus; if it lies within the curve, its distance from the directrix is greater than its distance from the focus.

1°. Let Q be a point lying without a parabola whose directrix is EG, and whose focus is F.

Draw QG perpendicular to EG and prolong it till it meets the curve at P; draw QF and PF.

In the triangle FQP, we have,

$$FP < FQ + QP;$$

or, since FP is equal to GP,

$$GP < FQ + QP.$$

If we subtract QP from both members of the last inequality, remembering that GP-QP is equal to GQ, we have,

$$GQ < FQ,$$

which was to be proved.

2°. Let R be a point lying within the curve.

Draw RG perpendicular to EG, cutting the curve at P; also draw RF and PF.

In the triangle FPR, we have,

$$FP + PR > FR;$$

But FP is equal to GP, and consequently $FP + PR$ is equal to GR; hence,

$$GR > FR,$$

which was to be proved.

Cor. If the distance of a point from EG is less than its distance from F, the point lies without the curve. For, if it were on the curve its distance from EG would be equal to its distance from F, or if it were within the curve its distance from EG would be greater than its distance from F.

PROPOSITION III. THEOREM.

The bisectrix of the angle formed by two lines drawn from any point of a parabola, one to the focus, and the other perpendicular to the directrix, is tangent to the curve at that point.

Let P be any point of a parabola whose directrix is EG and whose focus is F. Suppose PG to be perpendicular to EG, and let PT bisect the angle GPF.

Take any point, Q, of PT, except P, and draw QR perpendicular to EG; also draw QG, QF, and FG.

Because GP is equal to FP, and the angle GPT to TPF, the line PT is perpendicular to FG at its middle point, L; hence, GQ is equal to FQ, (P. 16, B. 1). But, RQ is less

than GQ , (P. 14, B. 1); hence, RQ is less than FQ ; consequently, Q lies without the curve, (P. 2, *Cor.*). Therefore, every point of PT , except P , lies without the parabola; hence, PT is tangent to the curve at P , *which was to be proved.*

Cor. 1. The line AK , perpendicular to EF at A is tangent to the parabola at A . It is called the **vertical tangent**.

Cor. 2. The angles FPT and GPT are equal by hypothesis, and FTP and GPT are equal because they are alternate angles; consequently, the triangle FTP is isosceles; hence, FT is equal to FP , that is, the focus is equally distant from the foot of the tangent, and from the point of contact.

Cor. 3. Because EA and AF are equal, and because AK is parallel to EG , AK passes through L ; hence, the perpendicular from the focus to any tangent, meets it at a point of the vertical tangent.

Definitions.

4. The **ordinate** of a point is the perpendicular distance from the axis to the point.

5. The **parameter** of a parabola is the double ordinate through the focus.

6. A **normal** is the perpendicular to a tangent at the point of contact.

7. A **subtangent** is the distance from the foot of the tangent to the foot of the ordinate of the point of contact.

8. A **subnormal** is the distance from the foot of the ordinate of the point of contact to the foot of the normal.

PROPOSITION IV. THEOREM.

The parameter of a parabola is equal to twice the distance from the directrix to the focus.

Let QAP be a parabola whose directrix is RG and whose focus is F; let QFP be perpendicular to EF, and let QB and PG be perpendicular to RG; then is QP, or 2FP, the parameter of the curve, (*Art. 5*).

From the definition of the parabola we have FP equal to GP; hence, 2FP is equal to 2GP, or to 2EF, *which was to be proved.*

* *Cor.* The distance from the vertex to the focus is equal to one-fourth of the parameter.

PROPOSITION V. THEOREM.

The subtangent is bisected at the vertex.

Let QAP be any parabola; P, any point of the curve; PT, the corresponding tangent; HP, the ordinate of P; and AL, the vertical tangent; then is TH the subtangent.

Draw FL perpendicular to PT; then, because FT is equal to FP, (P. 3, *Cor. 2*), TL is equal to LP. But from the similar triangles TAL and THP, we have,

$$TA : AH :: TL : LP;$$

hence, TA is equal to AH, *which was to be proved.*

PROPOSITION IX. THEOREM.

If a conic surface is cut by a plane whose inclination to the plane of the base is equal to that of an element of the surface, the section is a parabola.

Let SVR be any meridian plane of the conic surface whose vertex is V, and whose base is RLT; and let MPQ be a section parallel to the base. Let TQAPL be a section made by a plane perpendicular to SVR, having its inclination RKA equal to the angle RSV, and let this plane intersect the plane SVR in AK, the circle MPQ in QP, and the circle RST in TL.

The plane SVR divides the conic surface into two symmetrical parts, and because it is perpendicular to the planes TAL, MPQ, and RLT, it divides the corresponding curves symmetrically; hence, AK is the axis of TQAPL, MN is a diameter of MPQ, and RS is a diameter of RLT. Furthermore, HP is perpendicular to the plane SVR, (P. 14, Cor. 3, B. 6), and consequently to AK and MN; and for like reason, KL is perpendicular to AK and RS.

From P. 18, Cor., B. 3, we have,

$$\overline{HP}^2 = NH \times HM, \text{ and } \overline{KL}^2 = SK \times KR;$$

but, SK and NH are equal, because they are parallels between parallels; hence, the second members of these equations are equimultiples of HM and KR; consequently, we have,

$$\overline{HP}^2 : \overline{KL}^2 :: HM : KR. \quad . \quad . \quad . \quad (1)$$

From the similar triangles AHM and AKR, we have,

$$HM : KR :: AH : AK. \quad . \quad . \quad . \quad (2)$$

Hence, from (1) and (2), we have,

$$\overline{HP}^2 : \overline{KL}^2 :: AH : AK,$$

or,
$$\overline{HP}^2 = \frac{\overline{KL}^2}{AK} \times AH \dots (3)$$

But $\frac{\overline{KL}^2}{AK}$ is a fixed quantity, for a given position of the plane TAL; placing this equal to $2p$, we have,

$$\overline{HP}^2 = 2p \times AH.$$

Hence, from P. 8, *Scho.*, the section TQAPL is a parabola, *which was to be proved.*

II. THE ELLIPSE.

Definitions.

9. An **ellipse** is a plane curve that may be generated by a point, moving so that the sum of its distances from two fixed points is equal to a given line.

The moving point is called the **generatrix**; the fixed points are **foci**; the straight line through the foci, and limited by the curve, is the **transverse axis**; the point midway between the foci is the **centre**; the perpendicular to the transverse axis at the centre, and limited by the curve, is the **conjugate axis**; any line through the centre, and limited by the curve, is a **diameter**.

10. The **ordinate** of any point is its perpendicular distance from the transverse axis.

11. **Focal lines** of a point are lines from the foci to that point.

12. The **excentricity** is the distance from the centre to either focus, *divided by half the transverse axis*.

13. The **parameter of the curve** is the double ordinate through either focus.

PROPOSITION X. PROBLEM.

To construct an ellipse when the foci and one position of the generatrix are given.

Let F and F' be the foci, and P , any position of the generatrix; let PF and $F'P$ be focal lines drawn to P .

Take a string equal in length to the sum of FP and $F'P$, and fasten one end at F and the other end at F' ; then press a pencil against the string so as to make it tense, and move the pencil around F and F' ; the point of the pencil will trace out the required curve; for, in every position, the sum of its distances from the foci is equal to the length of the string.

Draw AC through F and F' , and it will be the transverse axis; through O , the middle of FF' , draw DE , perpendicular to AC , and it will be the conjugate axis.

Cor. 1. When the generatrix is at A , the sum of its focal lines is equal to $2AF + FF'$, and when it is at C , this sum is equal to $2CF' + FF'$; but, these sums are equal; hence, CF' is equal to AF , and consequently CO is equal to AO . Again, because $2AF + FF'$ is equal to $AF + FF' + F'C$, or to AC , the sum of the focal lines to any point of the curve is equal to the transverse axis.

Cor. 2. When the generatrix is at E , or at D , its focal

dicular to, and is bisected by, the transverse axis. Again, let the part DPE be revolved about DE through a half revolution; P will fall on the perpendicular PQ, making KQ equal to KP, F will fall on F', the line FP will fall on F'Q, and the angle OFP on the angle OF'Q; hence, the triangles FF'P and FF'Q are equal in all their parts, and consequently, Q is a point of the curve, that is, for every point P, there is a second point Q, such that the line joining them is perpendicular to, and is bisected by, the conjugate axis. Hence, the curve is symmetrical with respect to both of its axes, *which was to be proved.*

Cor. 1. The figure P'FQF' is a parallelogram, (P. 27, B. 1); hence, the angle FQF' is equal to $\angle F'F'P$, $\angle FQP'$ to $\angle QP'F'$, and $\angle F'QP'$ to $\angle FP'Q$.

Cor. 2. The diagonals of P'FQF' bisect each other, (P. 29, B. 1); but, P'Q is a diameter; hence, every diameter is bisected at the centre.

PROPOSITION XIII. THEOREM.

The bisectrix of the angle formed by one of the focal lines of a point of the curve, and the prolongation of the other focal line, is tangent to the curve at that point.

Let P be any point of an ellipse whose transverse axis is AC, and let FP and F'P be the corresponding focal lines; let PT bisect the angle between FP and the prolongation of F'P.

On the prolongation of F'P, lay off PQ equal to PF and

draw QF. Let R be any point of PT, except P, and draw RF, RF', and RQ.

Because PF is equal to PQ, and the angle FPK to QPK, PT is perpendicular to FQ, at its middle point, K; consequently, RQ is equal to RF. Now, in the triangle F'QR, we have,

$$F'R + RQ > F'Q;$$

but, RQ is equal to RF, and F'Q is equal to the sum of F'P and FP, or to AC; consequently,

$$F'R + FR > AC;$$

hence, R lies without the curve, (P. 11, *Cor.*), that is, every point of PT, except P, lies without the curve; PT is therefore tangent to the ellipse at P, *which was to be proved.*

Cor. 1. The angles FPT and F'PR are equal; for each is equal to QPK; either of these angles is half the supplement of FPF'.

Cor. 2. Perpendiculars to AC, at A and C, are tangents to the curve, at A and C.

PROPOSITION XIV. PROBLEM.

To draw a tangent to an ellipse at a given point.

Let P be any point of the ellipse whose foci are F and F'; let FP and F'P be the corresponding focal lines, and suppose F'P to be the greater. Lay off PK equal to PF and draw FK, forming the isosceles triangle

Now, the triangles OFK and OF'K' have the side OF equal to OF', the side OK to OK', and the angle FOK to F'OK'; hence, F'K' is equal to FK. But, RK' and AC are chords of the circle OA; hence, $RF' \times F'K'$, or $RF' \times FK$, is equal to $AF' \times F'C$, or to \overline{OE}^2 , (P. 10, Cor. 3), that is, *the product of the perpendiculars from the foci to any tangent is equal to the square of the semi-conjugate axis.*

Cor. 2. Because PT is perpendicular to FQ at its middle point, it bisects the angle F'TQ; hence, (P. 14, B. 3),

$$F'T : QT :: F'P : PQ,$$

but, QT is equal to FT, and PQ to PF; consequently,

$$F'T : FT :: F'P : FP.$$

Hence, by composition and division

$$F'T + FT : F'T - FT :: F'P + FP : F'P - FP,$$

$$\text{or, } 2OT : 2OF :: 2OA : F'P - FP. \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Scho. The circle OA is said to circumscribe the ellipse.

PROPOSITION XVII. THEOREM.

The semi-transverse axis of an ellipse is a mean proportional between the distance from the centre to the foot of the tangent,

and the distance from the centre to the foot of the ordinate of the point of contact.

Let PT be tangent to the ellipse whose centre is O ; let HP be the ordinate of the point of contact, and let $F'P$ and FP , be the focal lines of that point.

From the right-angled triangles $F'HP$ and FHP , we have,

$$\overline{F'P}^2 = \overline{F'H}^2 + \overline{HP}^2, \dots \dots \dots (1)$$

and

$$\overline{FP}^2 = \overline{FH}^2 + \overline{HP}^2. \dots \dots \dots (2)$$

Subtracting (2) from (1), member from member, we have,

$$\overline{F'P}^2 - \overline{FP}^2 = \overline{F'H}^2 - \overline{FH}^2,$$

whence, by factoring the two members,

$$(F'P + FP)(F'P - FP) = (F'H + FH)(F'H - FH);$$

but, $F'P + FP$ is equal to $2OA$, $F'H + FH$ to $2OF$, and $F'H - FH$ to $(F'O + OH) - (FO - OH)$, or to $2OH$; hence, the last equation becomes

$$2OA \times (F'P - FP) = 2OF \times 2OH,$$

or,

$$2OA : 2OH :: 2OF : F'P - FP. \dots \dots (3)$$

From proportion (1), P. 16, *Cor.* 2, we have, by alternation,

$$2OT : 2OA :: 2OF : F'P - FP; \dots \dots (4)$$

combining (4) and (3), and dividing each term by 2, we have

$$OT : OA :: OA : OH, \dots \dots \dots (5)$$

which was to be proved.

PROPOSITION XVIII. THEOREM.

The subtangent in an ellipse is equal to the corresponding subtangent in the circumscribing circle.

Let PT be tangent to the ellipse whose semi-transverse axis is OA, at any point, P; let the ordinate HP be prolonged till it meets the circumference OA at Q, and draw QT.

From P. 17, we have,

$$OT : OA :: OA : OH,$$

or,

$$OT : OQ :: OQ : OH.$$

Now, the triangles OQT and OHQ, have the angle QOT common, and from what has just been shown the including sides of this angle are proportional; hence, the triangles are similar; the angle OQT is therefore equal to OHP, that is, it is a right angle; hence, QT is tangent to the circumference OA at Q. The line HT is therefore a common subtangent, corresponding to the two tangents PT and QT, which was to be proved.

Scho. This principle is used in drawing a tangent to an ellipse at a given point as follows: let P be a given point on the ellipse; draw its ordinate, and prolong it to meet the circumscribing circumference at Q; draw QT perpendicular to the radius OQ, and from the point T, in which it meets the prolongation of the transverse axis, draw TP; this will be the required tangent.

PROPOSITION XIX. THEOREM.

The square of any ordinate of an ellipse is equal to the square of the ratio of the semi-axes, multiplied by the product of the segments into which the ordinate divides the transverse axis.

Let P be any point of the ellipse whose foci are F and F'. Let PT be tangent to the curve at P, and let FK and F'R be perpendicular to it.

Prolong the ordinate HP to meet the circumference OA, at Q, and draw QT; QT will be perpendicular to the radius OQ. The right-angled triangles THP, TKF, and TRF', have the angle at T in common; they are therefore similar; hence,

$$HP : FK :: HT : KT, \dots \dots \dots (1)$$

and,

$$HP : F'R :: HT : RT; \dots \dots \dots (2)$$

multiplying (1) by (2), term by term, we have,

$$\overline{HP}^2 : FK \times F'R :: \overline{HT}^2 : KT \times RT. \dots \dots (3)$$

But, (P. 16, Cor. 1), $FK \times F'R = \overline{OE}^2$, and, (P. 20, Cor., B. 3), $KT \times RT = \overline{QT}^2$; hence,

$$\overline{HP}^2 : \overline{OE}^2 :: \overline{HT}^2 : \overline{QT}^2. \dots \dots \dots (4)$$

From the similar triangles QHT and OHQ we have

$$HT : QT :: HQ : OQ, \text{ or } OA,$$

or,

$$\overline{HT}^2 : \overline{QT}^2 :: \overline{HQ}^2 : \overline{OA}^2; \dots \dots \dots (5)$$

combining (4) and (5), and replacing \overline{HQ}^2 by its value $AH \times HC$, we have

$$\overline{HP}^2 : \overline{OE}^2 :: AH \times HC : \overline{OA}^2,$$

or,

$$\overline{HP}^2 = \frac{\overline{OE}^2}{\overline{OA}^2} (AH \times HC), \dots \dots \dots (6)$$

which was to be proved.

Cor. 1. If H is taken at either focus, HP is one-half of the parameter of the curve, (*Art. 13*). In this case, the rectangle of the corresponding segments of the transverse axis is equal to \overline{OE}^2 , (*P. 10, Cor. 3*); denoting the *semi-parameter* by p , we have, from (6),

$$p^2 = \frac{\overline{OE}^2}{\overline{OA}^2} \times \overline{OE}^2, \text{ or } p^2 = \frac{\overline{OE}^4}{\overline{OA}^2};$$

extracting the square root of both members, we have,

$$p = \frac{\overline{OE}^2}{\overline{OA}}, \text{ or } 2p = \frac{4\overline{OE}^2}{2\overline{OA}};$$

hence, the proportion,

$$2\overline{OA} : 2\overline{OE} :: 2\overline{OE} : 2p,$$

that is, *the parameter is a third proportional to the transverse and conjugate axes.*

Cor. 2. In passing from point to point of the curve the square of the ratio of the semi-axes does not change; hence, *the squares of the ordinates of any two points of the ellipse are to each other as the rectangles of the segments into which they divide the transverse axis.*

Scho. The ultimate basis of the preceding corollary is the definition of the ellipse; hence, the property there enunciated is a characteristic property of the ellipse. It is to be observed that the segments alluded to are both *internal*, that is, their common extremity lies between the extremities of the transverse axis.

PROPOSITION XX. THEOREM.

The ordinate of any point of an ellipse, is to the ordinate of the corresponding point of the circumscribing circle, as the semi-conjugate axis, is to the semi-transverse axis.

Let HP be the ordinate of any point, P, of an ellipse, and let HQ be the corresponding ordinate of the circumscribing circle.

Let PT be tangent to the ellipse, at P, and QT tangent to the circle OA, at Q.

From P. 19, we have,

$$\overline{HP}^2 = \frac{\overline{OE}^2}{\overline{OA}^2} (AH \times HC), \quad \dots \dots (1)$$

and from P. 18, *Cor.*, B. 3, we have,

$$\overline{HQ}^2 = AH \times HC. \quad \dots \dots (2)$$

Dividing (1) by (2), member by member, we have,

$$\frac{\overline{HP}^2}{\overline{HQ}^2} = \frac{\overline{OE}^2}{\overline{OA}^2}, \quad \text{or} \quad \frac{HP}{HQ} = \frac{OE}{OA},$$

whence, $HP : HQ :: OE : OA,$

which was to be proved.

Scho. If OA remains unchanged, whilst OE increases, the ellipse approaches its circumscribing circle, and when OE becomes equal to OA, the ellipse coincides with the circle. Hence, the circle is a particular case of the ellipse; in this case, the foci of the ellipse coincide with the centre of the circle.

PROPOSITION XXI. THEOREM.

If a conic surface is cut by a plane, whose inclination to the plane of the base is less than that of an element of the surface, the section is an ellipse.

Let SVR be any meridian plane of the conic surface whose vertex is V, and whose base is RLT, and let MPQ be a section parallel to the base. Let APCT be a section of the surface by a plane perpendicular to SVR, and whose inclination, AKR, to the plane of the base, is less than VSR; and let the plane of this section intersect the circle MPQ in QP, and the circle RST in TL.

The plane SVR divides the surface into two symmetrical parts, and because it is perpendicular to the planes APCT, MNQ, and RST, it divides the corresponding curves symmetrically; hence, AC is the axis of the curve APCT, MN is a diameter of the circle MPQ, and RS is a diameter of the circle RLT. Furthermore, HP is perpendicular to AC, and MN, and TL is perpendicular to AC, and RS.

From P. 18, *Cor.*, B. 3, we have,

$$\overline{HP}^2 = NH \times HM, \quad \dots \dots \dots (1)$$

and, $\overline{KL}^2 = SK \times KR; \quad \dots \dots \dots (2)$

whence, $\overline{HP}^2 : \overline{KL}^2 :: NH \times HM : SK \times KR. \dots (3)$

From the similar triangles CNH and CSK, we have,

$$NH : SK :: HC : KC, \quad \dots \dots \dots (4)$$

and from the similar triangles AHM and AKR, we have,

$$HM : KR :: AH : AK. \quad . \quad . \quad . \quad . \quad (5)$$

Multiplying (4) and (5), term by term, we have,

$$NH \times HM : SK \times KR :: AH \times HC : AK \times KC. \quad . \quad . \quad (6)$$

From (3) and (6), we have,

$$\overline{HP}^2 : \overline{KL}^2 :: AH \times HC : AK \times KC,$$

which is a characteristic property of the ellipse, (P. 19, *Scho.*); hence, the section APCT is an ellipse, *which was to be proved.*

Cor. If the cutting plane is parallel to the base, the section is a circle, which is a particular case of the ellipse.

III. THE HYPERBOLA.

Definitions.

14. An **hyperbola** is a plane curve that may be generated by a point, moving so that the difference of its distances from two fixed points is equal to a given line.

The moving point is called the **generatrix**; the fixed points are **foci**; the straight line through the foci and limited by the curve is the **transverse axis**; the point midway between the foci is the **centre**; the perpendicular to the transverse axis at the centre is the **conjugate axis**; and any line through the centre, limited by the curve, is a **diameter**.

15. The **ordinate** of a point is its distance from the transverse axis, indefinitely prolonged.

16. **Focal lines** of a point are lines from the foci to that point.

17. The **excentricity** is the distance from the centre to either focus, divided by half the transverse axis.

18. The **parameter of the curve** is the double ordinate through the focus.

PROPOSITION XXII. PROBLEM.

To construct an hyperbola when the foci and the difference of the focal lines of any point of the curve are given.

Let F and F' be the foci. Fasten a ruler, FR , so that it can revolve about F' as a centre; then take a string, whose length differs from that of the ruler by the given difference of the focal lines, and fasten one extremity at F and the other

at R ; press the string against the ruler by a pencil, P , and revolve the ruler around F' ; the pencil will trace out a portion of the curve, for in every position we shall have $F'P - FP$ equal to the given difference between the focal lines.

If the string is shorter than the ruler the pencil will describe a part of the right-hand branch; if longer, the pencil will describe a part of the left-hand branch.

Cor. It may be shown, as in P. 10, *Cor.* 1, that the transverse axis is bisected at the centre, and that the difference between the focal lines of any point of the curve is equal to the transverse axis.

Scho. Although the conjugate axis, DE , does not cut the curve, it is nevertheless a definite line. It is bisected at the centre, and each

half is a mean proportional between the focal lines to either vertex of the transverse axis.

Let a circle be described on FF' as a diameter; then draw ML perpendicular to FF' , through A , and it will be equal to the conjugate axis. For,

$$\overline{AL}^2 = \overline{AF'} \times \overline{AF}.$$

PROPOSITION XXIII. THEOREM.

If a point lies without the hyperbola, the difference of its focal distances is less than the transverse axis; if it lies within the curve, the difference of its focal distances is greater than the transverse axis.

1°. Let Q lie without the hyperbola whose foci are F and F' , and whose transverse axis is AC .

Draw $F'Q$ and FQ ; from P , the point in which FQ cuts the curve, draw PF' .

In the triangle $PF'Q$, we have,

$$QF' < QP + PF';$$

subtracting QF from the first member, and its equal $QP + PF$ from the second member, we have,

$$QF' - QF < PF' - PF, \text{ or } AC,$$

which was to be proved.

2°. Let R lie within the curve.

Draw $F'R$ and FR ; prolong the latter till it meets the curve at P and draw PF' .

In the triangle $PF'R$, we have,

$$F'R + PR > PF',$$

subtracting $PR + FR$ from the first member, and its equal PF from the second member, we have,

$$F'R - FR > PF' - PF, \text{ or, } AC,$$

which was to be proved.

Cor. If the difference of the focal lines of a point is less than the transverse axis, the point is without the curve; if this difference is greater than the transverse axis, the point is within the curve; and if this difference is equal to the transverse axis, the point is on the curve.

Scho. It may be shown by a course of reasoning similar to that employed in P. 12 that the curve is symmetrical with respect to both axes, and that every diameter is bisected at the centre.

The axes are supposed to be indefinitely prolonged in both directions.

PROPOSITION XXIV. THEOREM.

The bisectrix of the angle between the focal lines of a point of the hyperbola, is tangent to the curve at that point.

Let P be a point of the curve, $F'P$ and FP , the corresponding focal lines, and PT , the bisectrix of the angle $F'PF$.

Lay off PQ equal to PF , and draw FQ cutting PT at K: then is $F'Q$ equal to AC , by definition. Take any point, R, of PT , and draw RF , RQ , and RF' .

Because FP is equal to QP, and the angle FPK to QPK, PT is perpendicular to FQ, at its middle point K; consequently, RQ is equal to RF.

Now, in the triangle $F'RQ$,
we have,

$$F'R - RQ < F'Q.$$

But, $F'R - RQ$ is equal to $F'R - FR$, and $F'Q$ is equal to AC ; hence,

$$F'R - FR < AC,$$

that is, every point of PT, except P, lies without the curve, (P. 23, Cor.); hence, PT is tangent to the curve at P, *which was to be proved*.

Cor. 1. To draw a tangent to the curve at any point: draw the corresponding focal lines and bisect the angle between them; the bisectrix is the required tangent.

Cor. 2. Because PT bisects the angle FPF', we have,

$$\mathbf{F}'\mathbf{T} : \mathbf{F}\mathbf{T} :: \mathbf{F}'\mathbf{P} : \mathbf{F}\mathbf{P};$$

whence, by composition and division,

$$\mathbf{F}'\mathbf{T} + \mathbf{F}\mathbf{T} : \mathbf{F}'\mathbf{T} - \mathbf{F}\mathbf{T} :: \mathbf{F}'\mathbf{P} + \mathbf{F}\mathbf{P} : \mathbf{F}'\mathbf{P} - \mathbf{F}\mathbf{P},$$

or,

$$20F : 20T :: F'P + FP : 20A. \quad . \quad . \quad . \quad (1)$$

Scho. 1. It may be shown by a course of reasoning similar to that in P. 15, that the tangents at the extremities of any diameter are parallel.

Scho. 2. It may be proved as in P. 16, that a perpendicular from either focus to any tangent intersects the tangent on the circumference of a circle whose diameter is the transverse axis, and that the product of the perpendiculars is equal to the square of the semi-conjugate axis.

Note. Let the student demonstrate the principles expressed in the scholiums of this and the preceding theorem.

PROPOSITION XXV. THEOREM.

The semi-transverse axis of an hyperbola is a mean proportional between the distance from the centre to the foot of the tangent, and the distance from the centre to the foot of the ordinate of the point of contact.

Let PT be tangent to the hyperbola at P; let O, be the centre, HP, the ordinate of P, and F'P and FP, its focal lines.

From the right-angled triangles F'HP and FHP, we have,

$$\overline{F'P}^2 = \overline{F'H}^2 + \overline{HP}^2, \dots \dots \dots (1)$$

and,

$$\overline{FP}^2 = \overline{FH}^2 + \overline{HP}^2; \dots \dots \dots (2)$$

subtracting (2) from (1), member from member, we have,

$$\overline{F'P}^2 - \overline{FP}^2 = \overline{F'H}^2 - \overline{FH}^2,$$

whence, by factoring, we have,

$$(F'P + FP)(F'P - FP) = (F'H + FH)(F'H - FH);$$

but, $F'P - FP$ is equal to AC , or to $2OA$, $F'H + FH$ is equal to $2OH$, and $F'H - FH$ is equal to FF' , or to $2OF$; hence, the preceding equation becomes,

$$(F'P + FP) \times 2OA = 2OH \times 2OF,$$

whence,

$$F'P + FP : 2OF :: 2OH : 2OA. \dots \dots (3)$$

From P. 24, Cor. 2, we have, by alternation and inversion,

$$F'P + FP : 2OF :: 2OA : 2OT, \dots (4)$$

combining (3) and (4), and dividing each term by 2, we have,

$$OH : OA :: OA : OT, \dots (5)$$

which was to be proved.

Cor. Through T, draw TQ, perpendicular to AC, meeting the circumference OA, at Q; also draw QO and QH; then, because OQ is equal to OA, we have from (5),

$$OH : OQ :: OQ : OT;$$

but, the triangles OQH and OTQ have a common angle TOQ, and since the sides about that angle are proportional, they are similar, and consequently, QH is perpendicular to OQ, that is, it is tangent to the circumference OA, at Q. Also (P. 18, Cor., and P. 19, B. 3),

$$\overline{TQ}^2 = AT \times TC = TK \times TR.$$

PROPOSITION XXVI. THEOREM.

The square of the ordinate of any point of an hyperbola, is equal to the square of the ratio of the semi-axes, multiplied by the rectangle of the distances from the foot of the ordinate to the extremities of the transverse axis.

Let P be any point on the hyperbola whose foci are F and F'. Let PT be tangent to the curve at P, and let FK and F'R be perpendicular to PT.

The right-angled triangles THP, TKF, and TRF', have an acute angle in each equal; they are therefore similar; hence,

that is, the parameter is a third proportional to the transverse and the conjugate axes.

Cor. 2. In passing from point to point of the curve the square of the ratio of the semi-axes does not change; hence, the squares of the ordinates of any two points of the curve are to each other as the rectangles of the distances from the foot of each, to the extremities of the transverse axis.

The distances HA and HC may be called *external segments* of CA, the point H being always on the prolongation of CA.

Scho. The preceding principle depends on the definition of the hyperbola; hence, the property in question is characteristic of the hyperbola.

PROPOSITION XXVII. THEOREM.

If a conic surface is cut by a plane whose inclination to the plane of the base is greater than that of an element of the surface, the section is an hyperbola.

Let SVR be a meridian plane of the conic surface whose vertex is V, and whose base is RLT, and let MPQ be a section parallel to the base. Let TQAPL be a portion of the section made by a plane perpendicular to SVR and whose inclination AKR, to the plane of the base, is greater than VSR; and let this plane intersect the circle MPQ in QP, and the circle RLT in TL. The plane will intersect the second nappe in the branch XCY, whose vertex is C.

For the reason before given, (P. 21), CAK is the principal axis of the curve, MN is a diameter of the circle MPQ, RS

is a diameter of the circle RLT, HP is perpendicular to AK and NM, and TL is perpendicular to AK and RS.

From the circles MPQ and RLT, we have, as in P. 21,

$$\overline{HP}^2 = NH \times HM,$$

and

$$\overline{KL}^2 = SK \times KR,$$

or,

$$\overline{HP}^2 : \overline{KL}^2 :: NH \times HM : SK \times KR. \quad (1)$$

From the similar triangles CNH and CSK, we have,

$$NH : SK :: HC : KC; \quad (2)$$

and from the similar triangles AHM and AKR, we have,

$$HM : KR :: HA : KA. \quad (3)$$

Multiplying (2) and (3), term by term, we have,

$$NH \times HM : SK \times KR :: HA \times HC : KA \times KC. \quad (4)$$

From (1) and (4) we have,

$$\overline{HP}^2 : \overline{KL}^2 :: HA \times HC : KA \times KC, \quad (5)$$

and because the points H and K are on the prolongation of CA, the distances HA, HC, KA and KC are *external segments* of CA. The property expressed by (5) is characteristic of the hyperbola, (P. 26, *Scho.*); hence, the section made by the plane TAL is an hyperbola, *which was to be proved.*

General Scholium. The parabola, the ellipse, and the hyperbola are conic sections.

TRIGONOMETRY.

I. INTRODUCTION—USE OF LOGARITHMS.

DEFINITIONS AND EXPLANATIONS.

1. The common logarithm of a number is the exponent of the power to which it is necessary to raise 10 to produce the given number; thus, 2 is the logarithm of 100, because $10^2 = 100$.

NOTE.—The principles used in this introduction are fully explained in the Manual of Algebra, chapter XI.

2. A logarithm consists of two parts; an entire part, called the **characteristic**, and a decimal part, called the **mantissa**. Either of these parts may be 0; thus, the logarithm of 6 is 0.778151 and the logarithm of 1000 is 3.000000; in the former the characteristic is 0, and in the latter the mantissa is 0.

The characteristic can always be found by the following

RULE.

If the number has an entire part, the characteristic of its logarithm is 1 less than the number of places of figures in that part; if the number is purely decimal, the characteristic

of its logarithm is negative and numerically greater by 1 than the number of ciphers that immediately follow the decimal point.

The characteristic of the logarithm of 425 is 2; that of .0425 is -2 ; if the characteristic is negative, the minus sign is written above the number; thus, -2 is written $\overline{2}$.

The mantissa, which is always positive, is entirely independent of the place of the decimal point; its value, in any given case, can be found from a table of logarithms, and in finding it, the decimal point may be moved to the right, or to the left, at pleasure.

Table of Logarithms.

3. The table appended to this volume gives the complete logarithms of all numbers from 1 to 100; it also gives the mantissas of the logarithms of all numbers from 100 to 10,000; by means of it, we can find approximate values for the mantissas of the logarithms of all numbers.

Use of the Table.

1°. *To find the logarithm of any number from 1 to 100.* Look for the number on the first page of the table in the column headed N; the number opposite in the column headed log., is the required logarithm; thus, $\log 16 = 1.204120$.

2°. *To find the logarithm of any number.* Find the characteristic by the rule already given. Then, drop the decimal point and find the mantissa as follows:

1st. If the number, after dropping the decimal point, contains four places of figures, let it stand; if it contains less than four places, annex ciphers enough to make four places; then look for the first three figures of the result in the column headed N, and follow the corresponding line across the page to the column headed by the fourth figure; if the

number there found contains *six* places of figures it is the required mantissa; if not, the *four* there found are the last four of the mantissa: to find the other two, follow the line back to the column headed 0, dropping to the line below if any *dots* are passed; then, if the number in that column has six places, prefix the first two to the four already found; if not, follow up the column headed 0 till a number is found which does contain six places, and prefix the first two of these. The result, preceded by a decimal point, is the required mantissa. It is to be observed that the *dots* stand for and are to be replaced by, ciphers.

Let the student verify the following equations:

1. $\log 2405 = 3.381115;$

2. $\log 380.6 = 2.580469;$

3. $\log 4.288 = 0.632255;$

4. $\log .0375 = \bar{2}.574031;$

5. $\log .005762 = \bar{3}.760573;$

6. $\log 37.11 = 1.569491.$

2d. If the number, after dropping the decimal point, contains more than four places of figures, place a new decimal point after the fourth figure, and find the mantissa of the entire part of the result, as just explained: then multiply the decimal part of the result by the number standing in the same line in the column D, and add the product to the mantissa already found. Thus, to find the logarithm of 478.632, we first find the characteristic, which is 2; then placing the decimal point after 6, we find the mantissa corresponding to 4786, which is .679973; we then multiply .32 by the tabular difference 91; the product is 29, and this we add to .679973, which gives .680002; hence, $\log 478.632 = 2.680002.$

Let the student verify the following equations:

1. $\log 3723.41 = 3.570941$;
 $\log .034621 = \bar{2}.539340$;
 $\log 99435 = 4.997539$;
 $\log 9.08085 = 0.958127$.

3°. To find the number corresponding to a given logarithm. This is done by reversing the preceding rules. The method of proceeding will be illustrated by examples.

Ex. 1. Find the number corresponding to the logarithm 2.314762.

OPERATION.

Given mantissa .314762

Next less in table .314710 . . Cor. number 2064.

$$D = \overline{210) 52} \begin{array}{l} .25 \end{array}$$

∴ Hence, $\log^{-1} 2.314762 = 206.425$, Ans.

Explanation.—We find the next less mantissa in the table and also the corresponding number. We then divide the difference of the mantissas by the corresponding number in the table under D ; we annex the quotient to the number taken out, dropping the decimal point : this gives 206425. We then point off three places from the left, because the characteristic is 2.

Note.—The symbol \log^{-1} is read, *the number whose logarithm is*.

Ex. 2. Find the number whose logarithm is $\bar{2}.960168$.

OPERATION.

Given mantissa .960168

Next less mantissa .960138 . . number 9123

$$D \quad . \quad . \quad . \quad \overline{48) 30} \begin{array}{l} (.6 \end{array}$$

∴ $\log^{-1} \bar{2}.960168 = 0.091236$, Ans.

Explanation.—The operation is the same as before, except in finding the mantissa ; on account of passing dots, the mantissa is found on two lines, the figures 96 being on one line, and the figures 0138 on the line above.

Let the student verify the following equations :

3. $\log^{-1} \bar{2}.573484 = 0.0374528$;
4. $\log^{-1} 0.342147 = 2.1986$;
5. $\log^{-1} 2.797948 = 627.984$;
6. $\log^{-1} \bar{3}.654210 = 0.00451034$;
7. $\log^{-1} \bar{2}.606032 = 0.040368$.

Multiplication by Logarithms.

4. To multiply two or more numbers together, we have the following

RULE.

Find the algebraic sum of the logarithms of the factors; this will be the logarithm of the product, and the corresponding number will be the product.

Ex. 1. Find the product of 3176 and 24.75.

OPERATION.

$$\log 3176 = 3.501880$$

$$\log 24.75 = \underline{1.393575}$$

$$\therefore \log^{-1} 4.895455 = 78605.82, \text{ Ans.}$$

Ex. 2. Find the product of 3.586, 2.0146, 0.8372, and 0.0294.

OPERATION.

$$\log 3.586 = 0.554610$$

$$\log 2.0146 = 0.304189$$

$$\log 0.8372 = \bar{1}.922829$$

$$\log 0.0294 = \bar{2}.468347$$

$$\therefore \log^{-1} \bar{1}.249975 = 0.17782, \text{ Ans.}$$

Note. The sum of the mantissas gives 2 to carry, and this added to the sum of the characteristics, which is -3 , gives -1 , or $\bar{1}$.

Division by Logarithms.

5. To divide one number by another, we have the following

R U L E .

Subtract (algebraically) the logarithm of the divisor from that of the dividend ; the difference is the logarithm of the quotient, and the corresponding number is the quotient.

Ex. 1. Divide 4.317 by 516.3.

OPERATION.

$$\log 4.317 = 0.635182$$

$$\log 516.3 = \underline{2.712902}$$

$$\therefore \log^{-1} 3.922280 = 0.0083614, \text{ Ans.}$$

Ex. 2. Divide 37.149 by 523.76.

Ans. 0.0709274.

Use of the Arithmetical Complement.

6. The arithmetical complement of a logarithm, denoted by the symbol $(a.c)$, is the result obtained by subtracting that logarithm from 10 ; thus $(a.c)$ 3.712745 is 6.287255. It may be found by beginning at the left and subtracting each figure from 9, to the last *significant* figure, which must be subtracted from 10.

If we denote the minuend by a , the subtrahend by b , and the remainder by r , we have,

$$r = a - b = a + (10 - b) - 10 = a + (a.c) b - 10 ;$$

hence, we may divide one number by another by the following

R U L E .

To the logarithm of the dividend add the arithmetical complement of the logarithm of the divisor and deduct 10 ; the number corresponding to the resulting logarithm is the required quotient.

Ex. 1. Divide 37.149 by 523.76.

OPERATION.

$$\begin{aligned}\log 37.149 &= 1.569947 \\ (a.c) \log 523.76 &= \underline{7.280867} \\ \therefore \log^{-1} \bar{2}.850814 &= 0.0709274, \text{ Ans.}\end{aligned}$$

Note. The 10 is subtracted mentally, in connection with the addition.

The preceding rules may be extended to finding the quotient of one continued product, by another. It is to be observed that 10 is to be subtracted every time that the arithmetical complement is used.

Ex. 2. Divide 23.7×34.56 , by 415.5×20.26 .

OPERATION.

$$\begin{aligned}\log 23.7 &= 1.374748 \\ \log 34.56 &= 1.538574 \\ (a.c) \log 415.5 &= 7.381429 \\ (a.c) \log 20.26 &= \underline{8.693361} \\ \therefore \log^{-1} \bar{2}.988112 &= 0.0973, \text{ Ans.}\end{aligned}$$

Solution of proportions by Logarithms.

7. A proportion, in which the fourth term is to be found, may be solved by the following

R U L E .

To the sum of the logarithms of the second and third terms, add the arithmetical complement of the logarithm of the first term, dropping 10 from the sum ; the number corresponding to the resulting logarithm is the required term.

Ex. Solve the proportion $2.714 : 0.1096 :: 43.7 : x$.

O P E R A T I O N .

$$\begin{array}{rcl}
 \log 0.1096 & = & \bar{1}.039811 \\
 \log 43.7 & = & 1.640481 \\
 (a \cdot c) \log 2.714 & = & \underline{9.566390} \\
 \therefore \log^{-1} 0.246682 & = & 1.7647, \text{ Ans.}
 \end{array}$$

Other applications.

8. We may raise a number to any power by multiplying the logarithm of the number, by the exponent of the power, and then finding the number that corresponds to the resulting logarithm. We may extract any root of a number by dividing the logarithm of the number, by the index of the root, and then finding the number that corresponds to the resulting logarithm.

Ex. 1. What is the cube of 5.152? *Ans.* 136.75.

Ex. 2. What is the cube root of 5.152? *Ans.* 1.72713.

Note. All the results obtained by means of logarithms are *approximate*.

II. CIRCULAR FUNCTIONS.

General definitions and explanations.

9. If the vertex of an angle is at the centre of a circle, the angle is measured by the arc intercepted by its sides

(see *measure of angles*, Art. 58, Geom.). Both the angle and the arc are expressed in *degrees*, *minutes*, and *seconds*, denoted by the symbols $^{\circ}$, $'$, $''$.

10. The complement of an arc, or angle, is equal to 90° minus the arc, or angle; thus, $43^{\circ} 15'$ is the complement of $46^{\circ} 45'$.

11. The supplement of an arc, or angle, is equal to 180° minus the arc, or angle; thus, $133^{\circ} 15'$ is the supplement of $46^{\circ} 45'$.

12. Arcs are compared by means of certain lines which depend on the arcs, and vary with them; these lines are called **circular functions**.

13. For the purpose of defining the circular functions, we draw a circle whose radius CA is equal to 1; we then draw its horizontal and vertical diameters, AB and DE. These divide the circumference into four quadrants of which AE is the *first*, EB the *second*, BD the *third*, and DA the *fourth*.

This circle, so divided, is called the **trigonometrical circle**; AB is called the **initial diameter**, and DE the **secondary diameter**.

The point A is called the **origin of arcs**, and all positive arcs are estimated from it around in the direction towards F. The point at which an arc terminates, is called its **extremity**. An arc is said to lie in that quadrant which contains its extremity; thus, the arc AF lies in the *first* quadrant, and AF' in the *second* quadrant.

In applying the trigonometrical circle to the measure of angles, we suppose the vertex of the angle to be at the centre of the circle, and so placed that its initial side shall coincide with CA.

Definitions of the circular functions.

14. The **sine** of an arc is the distance from the initial diameter to the extremity of the arc; thus, HF is the sine of the arc AF.

15. The **cosine** of an arc is the distance from the secondary diameter to the extremity of the arc; thus, GF is the cosine of AF.

The cosine is equal to the distance from the centre to the foot of the sine; thus, CH is equal to $\cos AF$.

16. The **tangent** of an arc is a line that touches the arc at its origin, and is limited by the prolongation of the diameter through its extremity; thus, AT is the tangent of the arc AF.

17. The **cotangent** of an arc is a line that touches the circumference at the extremity of the secondary diameter, and is limited by the prolongation of the diameter through the extremity of the arc; thus, EK is the cotangent of the arc AF.

18. The **secant** is the distance from the centre of the arc to the extremity of the tangent; thus, CT is the secant of AF.

19. The cosecant is the distance from the centre to the extremity of the cotangent; thus, CK is the cosecant of AF.

20. The versed sine is the distance from the foot of the sine to the origin of arcs; thus, HA is the versed sine of AF.

21. The covered sine is the distance from the foot of the cosine to the extremity of the secondary diameter; thus, GE is the covered sine of AF.

It is obvious from the figure that the cosine, the cotangent, the cosecant, and the covered sine of an arc, are respectively equal to the sine, the tangent, the secant, and the versed sine of the complement of the arc.

Because the supplement of an arc is as much greater than a quadrant as the arc itself is less, it follows that the sine of the supplement of an arc is equal to the sine of the arc, also that the tangent of the supplement of an arc is *numerically* equal to the tangent of the arc.

The circular functions of an arc, are the corresponding functions of the angle measured by that arc.

Tables of Circular Functions.

22. A table of natural sines and tangents is a table containing the values of those functions for all arcs, differing by 1 minute, from 0° to 90° , the radius being equal to 1.

23. A table of logarithmic sines and tangents is a table containing the logarithms of the natural sines and tangents, each logarithm being increased by 10.

The object of adding 10 to each logarithm is to avoid negative characteristics: thus, the natural sine of $37^\circ 28'$ is 0.6083 and its logarithm is $\bar{1}.784118$; by adding 10, we have the *tabular* logarithm 9.784118. The tens that are added are taken into account in the final result, as will be shown hereafter.

It is to be observed that the tabular logarithms, are the logarithms of the corresponding functions, in a circle whose radius is 10,000,000,000.

Explanation of the Table.

24. In the table appended to this work the logarithmic sines and tangents are given for every minute of the quadrant, and in the column D are the changes which these undergo for 1 second.

Because the cosine and the cotangent of an arc are respectively equal to the sine and the tangent of its complement, a table of sines and tangents may be used for finding the cosines and cotangents. To this end, the table is arranged in double columns, one corresponding to sines or tangents, and the other to cosines or cotangents.

For sines and cosines, the column of differences is placed to the right of each; for tangents and cotangents, it is placed between the two columns, and is common to both.

1°. *To find the logarithm of any function of an arc or angle.* If the arc, or angle, is less than 45° , look for the degrees at the top of the page and for the minutes in the left-hand column; then follow the corresponding line across the page to the column designated at *top* by the name of the function; or, if the arc or angle is greater than 45° , look for the degrees at the bottom of the page, and for the minutes in the right-hand column; then follow the corresponding line across the page to the column designated at *bottom* by the name of the function: take out the logarithm in this place, and set it aside. Also take out the corresponding number in the column D and multiply it by the number of seconds; then *add* the result to the logarithm set aside, for *sines* and *tangents*, and *subtract* it from that logarithm, for *cosines* and *cotangents*.

EXAMPLES.

1. Find the logarithmic sine of $18^\circ 23' 20''$.

OPERATION.

$$\log \sin 18^\circ 23' = 9.498825$$

$$D = 6.34$$

$$\underline{20}$$

$$126.80 \quad . \quad . \quad . \quad \text{add} \quad \underline{127}$$

$$\log \sin 18^\circ 23' 20'' = 9.498952, \text{ Ans.}$$

2. Find the logarithmic cotangent of $62^\circ 19' 30''$.

OPERATION.

$$\log \cot 62^\circ 19' = 9.719862$$

$$D = 5.12$$

$$\underline{30}$$

$$153.60 \quad . \quad . \quad . \quad \text{subtract} \quad \underline{154}$$

$$\log \cot 62^\circ 19' 30'' = 9.719708, \text{ Ans.}$$

Let the student verify the following equations:

3. $\log \sin 41^\circ 20' 15'' = 9.819868$;

4. $\log \cos 40^\circ 30' 10'' = 9.881028$;

5. $\log \sin 66^\circ 10' 50'' = 9.961337$;

6. $\log \cos 54^\circ 40' 30'' = 9.762088$;

7. $\log \tan 54^\circ 40' 30'' = 10.149541$;

8. $\log \cot 5^\circ 5' 5'' = 11.050713$;

2°. To find the arc, or angle, corresponding to a given logarithmic function. Look in the table for the next less logarithmic function of the same name: take out the corresponding degrees and minutes and set the result aside: also take out the corresponding value of D. Subtract the logarithm found in the table, from the given logarithm, and divide the remainder by the corresponding value of D; the quotient will be *seconds*, which must be *added* to the degrees and minutes set aside, in case of a *sine*, or *tangent*, and *subtracted*, in case of a *cosine*, or *cotangent*.

EXAMPLES.

1. Find the arc whose logarithmic sine is 9.516681.

OPERATION.

Given $\log \sin$. . . 9.516681

Next less in table . . 9.516657 . . arc $19^\circ 11'$

D . . . 6.05) 24 (4"

$\therefore \log \sin^{-1} 9.516681 = 19^\circ 11' 4''$, Ans.

Note.—The symbols $\log \sin^{-1}$, $\log \tan^{-1}$, &c., are to be read *the arc whose logarithmic sine is, the arc whose logarithmic tangent is, &c.*

2. Find the arc whose logarithmic tangent is 10.321287.

OPERATION.

Given $\log \tan$. . 10.321287

Next less in table . . 10.321179 . . arc $64^\circ 29'$

D . . 5.41) 108 (20"

$\therefore \log \tan^{-1} 10.321287 = 64^\circ 29' 20''$, Ans.

Let the student verify the following equations:

$$3. \log \sin^{-1} 9.634333 = 25^\circ 31' 19'';$$

$$4. \log \cos^{-1} 9.668135 = 62^\circ 14' 33'';$$

$$5. \log \tan^{-1} 10.364873 = 66^\circ 39' 10'';$$

$$6. \log \cot^{-1} 10.244220 = 29^\circ 40' 40''.$$

III. PLANE TRIGONOMETRY.

Definitions and explanations.

25. In every plane triangle there are six parts, three sides, and three angles. If three of these parts, one of which is a side, are given, or known, the other three may be found by computation.

26. The solution of a triangle is the operation of finding the remaining parts, when a sufficient number of parts are given.

27. Plane Trigonometry is that branch of Trigonometry which treats of the solution of plane triangles.

Method of proceeding.

28. The general method of proceeding is as follows:

We first deduce general equations expressing the relations between the parts of a triangle; we next transform these equations so as to adapt them to logarithmic computation; and then, we apply the resulting formulas to particular cases.

Principles used in solving right-angled triangles.

29. Let the triangle CAD be right-angled at A. Denote its hypotenuse, CD, by h ; its base, CA, by b ; and its altitude, or perpendicular, AD, by p .

From C as a centre, with a radius CE, equal to 1, draw the arc EF; also, draw ET and FH perpendicular to CA; then is HF the sine of the angle C, CH is its cosine, and ET its tangent.

Because the triangles CHF, CET, and CAD, are similar, we have,

$$CF : FH :: CD : DA; \text{ or, } 1 : \sin C :: h : p; . (1)$$

$$CF : CH :: CD : CA; \text{ or, } 1 : \cos C :: h : b; . (2)$$

$$CE : ET :: CA : AD; \text{ or, } 1 : \tan C :: b : p; . (3)$$

whence,

$$p = h \sin C; \text{ or, } \sin C = \frac{p}{h}; . . . (4)$$

$$b = h \cos C; \text{ or, } \cos C = \frac{b}{h}; \dots (5)$$

$$p = b \tan C; \text{ or, } \tan C = \frac{p}{b}; \dots (6)$$

From equations (4), (5) and (6), we have the following general principles:

1°. *The perpendicular, is equal to the hypotenuse, into the sine of the angle at the base; and the sine of the angle at the base, is equal to the perpendicular, divided by the hypotenuse.*

2°. *The base, is equal to the hypotenuse, into the cosine of the angle at the base; and the cosine of the angle at the base, is equal to the base, divided by the hypotenuse.*

3°. *The perpendicular, is equal to the base, into the tangent of the angle at the base; and the tangent of the angle at the base, is equal to the perpendicular, divided by the base.*

In what precedes the *sine*, *cosine*, and *tangent* of C are *natural* functions. It is to be observed that either one of the acute angles may be taken as the angle at the base, in which case, the side opposite is to be regarded as the perpendicular, and the side adjacent as the base.

Logarithmic Formulas.

30. By the rule for multiplication by logarithms, (*Art.* 4), we have from the first of equations (4),

$$\log p = \log h + \log \text{nat} \sin C;$$

adding 10 to, and subtracting 10 from, the second member, we have,

$$\log p = \log h + (\log \text{nat} \sin C + 10) - 10;$$

but, $\log \text{nat} \sin C + 10$ is the tabular logarithm of $\sin C$, (*Art.* 23), and is denoted by the symbol $\log \sin$; hence,

$$\log p = \log h + \log \sin C - 10. \quad . \quad . \quad . \quad (A)$$

By the rule for division by logarithms, (*Arts.* 5 and 6), we have from the second of equations (4),

$$\log \text{nat} \sin C = \log p + (a \cdot c) \log h - 10;$$

adding 10 to both members, remembering that the first member increased by 10 is the tabular logarithm of $\sin C$, we have,

$$\log \sin C = \log p + (a \cdot c) \log h; \quad . \quad . \quad . \quad (B)$$

in like manner, we have, from equations (5) and (6), the following formulas :

$$\log b = \log h + \log \cos C - 10; \quad . \quad . \quad . \quad (C)$$

$$\log \cos C = \log b + (a \cdot c) \log h; \quad . \quad . \quad . \quad (D)$$

$$\log p = \log b + \log \tan C - 10; \quad . \quad . \quad (E)$$

$$\log \tan C = \log p + (a \cdot c) \log b. \quad . \quad . \quad (F)$$

From (C) we have, by transposition,

$$\log h = \log b + (10 - \log \cos C)$$

or,

$$\log h = \log b + (a \cdot c) \log \cos C. \quad . \quad . \quad . \quad (G)$$

In applying the preceding formulas, only approximate results are to be expected. In what follows we shall compute angles to within $5''$ and sides to within .01, in accordance with the principle laid down in Art. 90, COMPLETE ARITHMETIC. In accordance with this principle the seconds in any result will be some multiple of $10''$.

Applications.

31. In the solution of right-angled triangles there are two cases: in the *first*, we have given one acute angle, and one side; in the *second*, we have given any two sides.

CASE 1°. *Given, an acute angle, and any side, to find the remaining parts.*

The other acute angle is found by subtracting the given one from 90° . The remaining sides may be found from formulas (A), (C), (E), and (G).

EXAMPLES.

1. Given, the angle at the base $40^\circ 20'$, and the hypotenuse 450 *yds.*, to find the other parts.

OPERATION.

1°. Angle at the vertex $= 90^\circ - 40^\circ 20' = 49^\circ 40'$.

2°. From formula (A),

$$\log h = \log 450 \quad . \quad . \quad . \quad 2.653213$$

$$\log \sin C = \log \sin 40^\circ 20' \quad . \quad \underline{9.811061}$$

$$\therefore \text{perpendicular} = \log^{-1} 2.464274 = 291.26 \text{ yds.}$$

3°. From formula (C),

$$\log h = \log 450 \quad . \quad . \quad . \quad 2.653213$$

$$\log \cos C = \log \cos 40^\circ 20' \quad . \quad \underline{9.882121}$$

$$\therefore \text{base} = \log^{-1} 2.535334 = 343.03 \text{ yds.}$$

2. Given, the angle at the vertex $39^\circ 50'$, and the hypotenuse 497 *ft.*, to find the other parts.

OPERATION.

1°. Angle at base $= 90^\circ - 39^\circ 50' = 50^\circ 10'$.

2°. From formula (A),

$$\log h = \log 497 \quad . \quad . \quad . \quad 2.696356$$

$$\log \sin C = \log \sin 50^\circ 10' \quad . \quad \underline{9.885311}$$

$$\therefore \text{perpendicular} = \log^{-1} 2.581667 = 381.65 \text{ ft.}$$

4°. From formula (C),

$$\log h = \log 497 \quad . \quad . \quad . \quad 2.696356$$

$$\log \cos C = \log \cos 50^\circ 10' \quad . \quad \underline{9.806557}$$

$$\therefore \text{base} = \log^{-1} 2.502913 = 318.36 \text{ ft.}$$

3. Given, the angle at the base $50^{\circ} 23'$, and the base 290 yds., to find the other parts.

OPERATION.

1°. Angle at the vertex $= 90^{\circ} - 50^{\circ} 23' = 39^{\circ} 37'$.

2°. From formula (E),

$$\log b = \log 290 \quad . \quad . \quad . \quad 2.462398$$

$$\log \tan C = \log \tan 50^{\circ} 23' \quad . \quad 10.082095$$

$$\therefore \text{perpendicular} = \log^{-1} 2.544493 = 350.34 \text{ yds.}$$

3°. From formula (G),

$$\log 290 \quad . \quad . \quad . \quad 2.462398$$

$$(a \cdot c) \log 50^{\circ} 23' \quad . \quad . \quad 0.195419$$

$$\therefore \text{hypotenuse} = \log^{-1} 2.657817 = 369.58 \text{ yds.}$$

4. Given, the angle at the vertex, $44^{\circ} 2'$, and the perpendicular, 84 yds., to find the other parts.

$$\text{Ans. } C = 45^{\circ} 58', b = 81.21 \text{ yds., } h = 116.84 \text{ yds.}$$

5. Given, the angle at the vertex, $36^{\circ} 15' 30''$, and the hypotenuse, 112 ft., to find the other parts.

$$\text{Ans. } C = 53^{\circ} 44' 30'', b = 66.24 \text{ ft., } p = 90.31.$$

6. Given, the angle at the base, $41^{\circ} 24' 30''$, and the hypotenuse, 397 ft., to find the other parts.

$$\text{Ans. } D = 48^{\circ} 35' 30'' b = 297.76 \text{ ft., } p = 262.58 \text{ ft.}$$

7. Given, $C = 14^{\circ} 37' 40''$, and $b = 111$ yds., to find the other parts.

$$\text{Ans. } D = 75^{\circ} 22' 20'', p = 28.97 \text{ yds., } h = 114.72 \text{ yds.}$$

8. Given, $D = 27^{\circ} 0' 25''$, and $p = 114$ in., to find the other parts.

$$\text{Ans. } C = 62^{\circ} 59' 35'', b = 58.1 \text{ in., } h = 127.95 \text{ in.}$$

CASE 2°. Given any two sides, to find the remaining parts.

The angle at the base may be found by one of the formulas (B), (D), or (F); the solution is then completed as in Case 1°.

EXAMPLES.

1. Given, the hypotenuse, 640 *yds.*, and the perpendicular, 300 *yds.*, to find the other parts.

OPERATION.

1°. From formula (B),

$$\log p = \log 300 \quad . \quad . \quad . \quad 2.477121$$

$$(a \cdot c) \log h = (a \cdot c) \log 640 \quad . \quad \underline{7.193820}$$

$$\therefore C = \log \sin^{-1} 9.670941 = 27^{\circ} 57' 10''.$$

$$2^{\circ}. D = 90^{\circ} - 27^{\circ} 57' 10'' = 62^{\circ} 2' 50''.$$

3°. From formula (C), we find $b = 565.33$ *yds.*

2. Given, the hypotenuse, 392 *ft.*, and the base, 256 *ft.*, to find C, D, and p .

OPERATION.

1°. From formula (D),

$$\log 256 \quad . \quad . \quad . \quad . \quad 2.408240$$

$$(a \cdot c) \log 392 \quad . \quad . \quad . \quad . \quad \underline{7.406714}$$

$$\therefore C = \log \cos^{-1} 9.814954 = 49^{\circ} 13' 40''$$

$$2^{\circ}. D = 90^{\circ} - 49^{\circ} 13' 40'' = 40^{\circ} 46' 20''.$$

3°. From formula (B), we find $p = 296.87$.

3. Given, the perpendicular, 360 *yds.*, and the base, 270 *yds.*, to find C, D, and h .

OPERATION.

1°. From formula (F),

$$\log 360 \quad . \quad . \quad . \quad . \quad 2.556303$$

$$(a \cdot c) \log 270 \quad . \quad . \quad . \quad . \quad \underline{7.568636}$$

$$\therefore C = \log \tan^{-1} 10.124939 = 53^{\circ} 7' 50''.$$

$$2^{\circ}. D = 90^{\circ} - 53^{\circ} 7' 50'' = 36^{\circ} 52' 10''.$$

3°. From formula (G), we find $h = 450$ *yds.*

Note.—The hypotenuse may be found without the use of logarithms from the formula, $h^2 = p^2 + b^2$.

4. Given, $h = 718$ yds., and $b = 425$ yds., to find the other parts.

Ans. $C = 53^\circ 42' 20''$, $D = 36^\circ 17' 40''$, $p = 578.7$ yds.

5. Given, $h = 420$ ft., and $p = 320$ ft., to find the other parts. *Ans.* $C = 49^\circ 38'$, $D = 40^\circ 22'$, $b = 272.02$ ft.

6. Given, $p = 99$ yds., and $b = 132$ yds., to find the other parts.

Ans. $C = 36^\circ 52' 10''$, $D = 53^\circ 7' 50''$, $h = 164.99$ yds.

7. Given, $p = 446$ ft., and $b = 810$ ft., to find the other parts.

Ans. $C = 28^\circ 50' 20''$, $D = 61^\circ 9' 40''$, $h = 924.68$ ft.

Principles used in solving oblique triangles.

32. In what follows the angles of a triangle will be denoted by A , C , and D ; and their opposite sides by a , c , and d .

First. From the vertex D , of the triangle ACD , draw DH perpendicular to the base, AC ; H may lie on CA , or it may lie on the prolongation of CA ; in the

latter case, the angle DAH is the supplement of A , and consequently, $\sin DAH$ is equal to $\sin A$; in both cases, we have, (Pr. 1°, Art. 29),

$$DH = a \sin C, \text{ and } DH = c \sin A,$$

whence,

$$a \sin C = c \sin A,$$

or,

$$a : c :: \sin A : \sin C; \quad . \quad . \quad . \quad . \quad (1)$$

hence, the following principle:

1°. *Any two sides of a plane triangle are to each other as the sines of their opposite angles.*

Secondly. Let ACD be a triangle, in which CD is less than DA .

From D as a centre, with the radius DC , describe the arc FCE , cutting AD at F , and the prolongation of AD at E ; draw EC and CF ; also, through F , draw FK parallel to EC ; then will ECF and CFK be right angles.

Because CDE is an exterior angle of the triangle, it is equal to $C + A$; but, CDE is an angle at the centre, and CFE is an inscribed angle, subtended by the same arc; hence,

$$CFE = \frac{1}{2}(C + A). \quad \dots \dots (2)$$

Because CFE is an exterior angle of the triangle ACF , we have,

$$\frac{1}{2}(C + A) = ACF + A,$$

or,

$$ACF = \frac{1}{2}(C - A). \quad \dots \dots (3)$$

From the right-angled triangles FCE and CFK , we have, (*Prin. 3°, Art. 29*),

$$EC = CF \tan \frac{1}{2}(C + A),$$

and,

$$FK = CF \tan \frac{1}{2}(C - A);$$

whence,

$$EC : FK :: \tan \frac{1}{2}(C + A) : \tan \frac{1}{2}(C - A). \quad \dots (4)$$

Because DF and DE are each equal to DC , AE is equal to $c + a$, and AF is equal to $c - a$. From the similar triangles AEC and AFK , we have,

$$AE : AF :: EC : FK,$$

or,

$$c + a : c - a :: EC : FK; \quad \dots \dots (5)$$

from (4) and (5), we have,

$$c + a : c - a :: \tan \frac{1}{2}(C + A) : \tan \frac{1}{2}(C - A); \quad (6)$$

hence, the following principle:

2°. *The sum of two sides of a plane triangle is to the difference of those sides, as the tangent of half the sum of their opposite angles, is to the tangent of half the difference of those angles.*

Thirdly. From the vertex D, of the triangle ACD, draw DH perpendicular to the base AC, dividing it into the segments CH and HA; the vertex D can always be chosen so that H shall fall between A and C. Denote CH by S, and HA by S'.

From the right-angled triangles CHD and AHD, we have,

$$a^2 = S^2 + \overline{DH}^2, \text{ and } c^2 = S'^2 + \overline{DH}^2;$$

whence, by subtraction,

$$a^2 - c^2 = S^2 - S'^2, \text{ or, } (a+c)(a-c) = (S+S')(S-S'),$$

or,

$$a + c : S + S' :: S - S' : a - c; \quad \dots (7)$$

hence, we have the following principle:

3°. *The sum of two sides, is to the sum of the corresponding segments of the third side, as the difference of these segments, is to the difference of the two sides.*

Logarithmic Formulas.

33. From proportion (1), Art. 32, we have,

$$a = \frac{c \sin A}{\sin C}, \text{ and } \sin A = \frac{a \sin C}{c};$$

whence, from the rules for multiplication and division by logarithms, we have,

$$\log a = \log c + \log \text{nat sin } A + (a \cdot c) \log \text{nat sin } C - 10, . \quad (1)$$

and,

$$\log \text{nat sin } A = \log a + \log \text{nat sin } C + (a \cdot c) \log c - 10. \quad (2)$$

Because the logarithm of a natural function is less by 10 than the corresponding tabular logarithm, the arithmetical complement of that logarithm is greater by 10 than the arithmetical complement of the corresponding tabular logarithm; hence, the form of equation (1) will not change in passing to tabular logarithms, and we shall have,

$$\log a = \log c + \log \sin A + (a \cdot c) \log \sin C - 10. \quad (H)$$

If we pass to tabular logarithms, by adding 10 to both members of (2), we have,

$$\log \sin A = \log a + \log \sin C + (a \cdot c) \log c - 10. . \quad (I)$$

From proportion (6), *Art.* 32, and by the rule for solving proportions by logarithms, we have,

$$\begin{aligned} \log \text{nat tan } \frac{1}{2} (C-A) &= \log (c-a) + \log \text{nat tan } \frac{1}{2} (C+A) \\ &+ (a \cdot c) \log (c+a) - 10; \end{aligned}$$

and passing to tabular logarithms, we have,

$$\begin{aligned} \log \tan \frac{1}{2} (C-A) &= \log (c-a) + \log \tan \frac{1}{2} (C+A) \\ &+ (a \cdot c) \log (c+a) - 10. \quad (K) \end{aligned}$$

From proportion (7), *Art.* 32, we have,

$$\begin{aligned} \log (S-S') &= \log (a+c) + \log (a-c) + (a \cdot c) \log (S+S') \\ &- 10. \quad (L) \end{aligned}$$

Applications.

34. In the solution of oblique triangles there are *four* cases.

CASE 1°. *Given, one side and two angles, to find the other parts.*

The third angle may be found by subtracting the sum of the given angles from 180° ; after which, the required sides may be found by formula (H).

· EXAMPLES.

1. Given, $d = 350$ yds., $A = 39^\circ 40'$, and $C = 47^\circ 20'$, to find the other parts.

OPERATION.

$$1^\circ. D = 180^\circ - (39^\circ 40' + 47^\circ 20') = 93^\circ.$$

2°. From formula (H), by changing c and C , into d and D , we have,

$$\log a = \log d + \log \sin A + (a \cdot c) \log \sin D - 10.$$

$$\log d = \log 350. \quad . \quad . \quad . \quad . \quad . \quad . \quad 2.544068$$

$$\log \sin A = \log \sin 39^\circ 40' \quad . \quad . \quad . \quad 9.805039$$

$$(a \cdot c) \log \sin D = (a \cdot c) \log \sin 93^\circ. \quad 0.000596$$

$$\therefore a = \log^{-1} 2.349703 = 223.72 \text{ yds.}$$

Note.—Because the sine of an angle is equal to the sine of its supplement, $\log \sin 93^\circ$ is equal to $\log \sin 87^\circ$.

3°. From formula (H), by changing a and A , into c and C , also c and C , into d and D , we have,

$$\log c = \log d + \log \sin C + (a \cdot c) \log \sin D - 10.$$

and consequently, its value may be computed; let it be denoted by p . We shall then have the following results:

First. If C is acute, and if c is less than a , but greater than p , there will be *two* solutions.

Secondly. If C is acute, and if c is equal to p ; or, if C is either acute or obtuse, and if c is greater than a , there will be but *one* solution.

Thirdly. If c is less than p , there is *no* solution. In the present example p is equal to 69.88, and consequently, there are two solutions.

$$2^\circ. D = 180^\circ - (30^\circ 40' + 56^\circ 17' 20'') = 93^\circ 2' 40'',$$

$$\text{and, } D' = 180^\circ - (30^\circ 40' + 123^\circ 42' 40'') = 25^\circ 37' 20''.$$

3°. From formula (H), we find,

$$d = 164.46, \text{ and } d' = 71.22.$$

2. Given, $A = 32^\circ$, $a = 200$, and $c = 250$, to find the other parts.

$$\text{Ans. } \begin{cases} C = 41^\circ 29', & D = 106^\circ 31', & d = 361.84 \\ C' = 138^\circ 31', & D' = 9^\circ 29', & d' = 62.18. \end{cases}$$

3. Given, $C = 36^\circ 30'$, $a = 64$, and $c = 96$, to find the remaining parts.

$$\text{Ans. } A = 23^\circ 21' 50'', \quad D = 120^\circ 8' 10'', \quad d = 139.58.$$

CASE 3°. *Given two sides and their included angle, to find the other parts.*

The half sum of the required angles is found by subtracting the given angle from 180° , and dividing the result by 2; the half difference of these angles is found by means of formula (K); and the remaining side is then found by formula (H).

EXAMPLES.

1. Given, $a = 90$, $c = 108$, and $D = 80^\circ$, to find the other parts.

$$1^\circ. \frac{1}{2}(C + A) = \frac{1}{2}(180^\circ - 80^\circ) = 50^\circ;$$

$$(c + a) = 108 + 90 = 198; \text{ and } (c - a) = 108 - 90 = 18.$$

From formula (K),

$$\begin{array}{rcl} \log 18 & . & . & . & . & 1.255273 \\ \log \tan 50^\circ & . & . & . & . & 10.076187 \\ (a \cdot c) \log 198 & . & . & . & . & 7.703335 \\ \hline \frac{1}{2}(C - A) = \tan^{-1} 9.034795 & = & 6^\circ 11'. \end{array}$$

Adding the half difference to the half sum, we find C, and subtracting the half difference from the half sum, we have A; hence,

$$C = 50^\circ + 6^\circ 11' = 56^\circ 11', \text{ and } A = 50^\circ - 6^\circ 11' = 43^\circ 49';$$

2°. From formula (H), we find $d = 128$.

2. Given, $c = 843$, $a = 480$, and $D = 128^\circ 4'$, to find the other parts.

$$\text{Ans. } A = 18^\circ 21' 20'', C = 33^\circ 34' 40'', d = 1200.$$

3. Given, $c = 16.96$, $a = 11.96$, and $D = 60^\circ 43' 40''$, to find the other parts.

$$\text{Ans. } C = 76^\circ 4' 40'', A = 43^\circ 11' 40'', d = 15.24.$$

CASE 4°. *Given the three sides, to find the other parts.*

In this case we take the longest side as a base, and from the opposite vertex, we draw a perpendicular to this base, dividing it into two segments; the sum of these segments is equal to the base, and their difference is found by formula L; then, the greater segment is equal to half their sum, *plus* half their difference, and the less segment is equal to half their sum, *minus* half their difference. It is to be remembered that the greater segment lies next the greater side, and

the less segment next the less side. After the segments are found, the angles at the base may be determined by formula (D), and the angle at the vertex may be found as before.

EXAMPLES.

1. Given $a = 144$, $c = 108$, and $d = 200$, to find the other parts.

1°. $a + c = 252$, $a - c = 36$, $S + S' = d = 200$.

∴ from formula (L), we have,

$$\begin{array}{rcl} \log 252 & . & . & . & . & . & 2.401401 \\ \log 36 & . & . & . & . & . & 1.556303 \\ (a \cdot c) \log 200 & . & . & . & . & . & \underline{7.698970} \end{array}$$

$$\therefore S - S' = \log^{-1} 1.656674 = 45.36.$$

$$\therefore S = \frac{1}{2}(200 + 45.36) = 122.68,$$

and,

$$S' = \frac{1}{2}(200 - 45.36) = 77.32.$$

2°. From formula (D), we have,

$$\begin{array}{rcl} \log S = \log 122.68 & . & . & 2.088774 \\ (a \cdot c) \log a = (a \cdot c) \log 144 & . & . & \underline{7.841638} \end{array}$$

$$C = \log \cos^{-1} 9.930412 = 31^\circ 34' 30''.$$

and,

$$\begin{array}{rcl} \log S' = \log 77.32 & . & . & 1.888292 \\ (a \cdot c) \log c = (a \cdot c) \log 108 & . & . & \underline{7.966576} \end{array}$$

$$\therefore A = \log \cos^{-1} 9.854868 = 44^\circ 16' 50''.$$

$$3^\circ. D = 180^\circ - (31^\circ 34' 30'' + 44^\circ 16' 50'') = 104^\circ 8' 40''.$$

2. Given, $a = 55$, $c = 44$, and $d = 66$, to find the other parts.

$$\text{Ans. } A = 55^\circ 46' 20'', C = 41^\circ 24' 30'', D = 82^\circ 49' 10''.$$

3. Given, $a = 136$, $c = 100$, and $d = 160$, to find the other parts.

Ans. $A = 57^\circ 41' 20''$, $C = 38^\circ 25' 20''$, $D = 83^\circ 53' 20''$.

4. Given, $a = 648$, $c = 374$, and $d = 712$, to find the other parts.

Ans. $A = 64^\circ 46' 50''$, $C = 31^\circ 28' 30''$, $D = 83^\circ 44' 40''$.

IV. ANALYTICAL TRIGONOMETRY.

Definitions and explanations.

35. Analytical trigonometry treats of the general relations of *circular functions*.

In considering the general relations of circular functions, the arc is supposed to have any value from 0° to 360° ; the figure shows these functions for arcs, terminating in each of the four quadrants. Sines and tangents are estimated from the initial diameter AB, either *upward*, or *downward*; cosines and cotangents are estimated from the secondary diameter ED, either *to the right*, or *to the left*. The algebraic signs of these functions are determined in accordance with the following

R U L E .

Distances estimated upward are plus, and those estimated downward are minus; distances estimated toward the right are plus, and those estimated toward the left are minus.

whence,
$$\operatorname{cosec} x = \frac{1}{\sin x} \dots \dots \dots (5)$$

If we multiply (2) by (4), member by member, we have,

$$\tan x \cot x = 1. \dots \dots \dots (6)$$

To these formulas, we may add the following, which are obvious from a simple inspection of the figure :

$$\operatorname{versin} x = 1 - \cos x, \text{ and } \operatorname{coversin} x = 1 - \sin x; \dots (7)$$

$$\sec^2 x = 1 + \tan^2 x, \text{ and } \operatorname{cosec}^2 x = 1 + \cot^2 x. \dots (8)$$

The following method of expressing the relations between the functions of any angle, and also the relations between the parts of a right-angled triangle, is due to Prof. J. W. Nicholson, of Louisiana.

Let ACD be a triangle, right-angled at A. Denote the angle at the base by C, the hypotenuse by h , the perpendicular by p , and the base by b . Then, let the sides of the triangle, and the several functions of C, be arranged as shown in the diagram. The nine elements, thus expressed, are called *parts*; the two parts that lie next to a given part, whether counted along a chord, or around the circumference, are said to be *adjacent* to it; and any two parts that are separated by two intervening parts are said to be *opposite* to each other. In all cases we have the following relations :

- 1°. Any part is equal to the product of its adjacent parts ;
- 2°. Any part is equal to the reciprocal of its opposite part.

Signs of circular functions in different quadrants.

37. In accordance with the rule for signs, in *Art.* 35, it is plain that the sine of an arc in the first, or in the second quadrant, is *plus* ; and that the sine of an arc in the third, or in the fourth quadrant, is *minus* ; also, the cosine of an arc in the first, or in the fourth quadrant, is *plus* ; and the

cosine of an arc in the second, and in the third quadrant, is *minus*. If due regard is paid to the rule for signs, the formulas of *Art.* 36 will hold true for all values of the arc from 0 to 360°. Applying what precedes to the formulas of *Art.* 36, we may form the following

TABLE.

ARC.	SIN.	COS.	TAN.	COT.	SEC.	COSEC.
1st quad.	+	+	+	+	+	+
2d quad.	+	—	—	—	—	+
3d quad.	—	—	+	+	—	—
4th quad.	—	+	—	—	+	—

Functions of negative arcs.

38. If an arc is estimated from the origin A, around toward F''', it is said to be *negative*. It is obvious that, the sine of a negative arc is equal to that of an equal positive arc, with its algebraic sign changed, and that the cosine of a negative arc is equal to that of an equal positive arc; hence, from the formulas of *Art.* 36, we have,

$$\sin (-x) = -\sin x, \cos (-x) = \cos x, \tan (-x) = -\tan x, \\ \text{and } \cot (-x) = -\cot x.$$

Limiting Values.

39. The limiting values of a circular function are its values when the arc is some multiple of a quadrant. In determining the sign of a limiting value, it is to be remembered that the sign of a varying magnitude up to the limit, is its sign at the limit. If we now suppose the arc to commence at 0°, and to increase by insensible increments up to 360°, we shall have the following results:

$\sin 0^\circ = +0$, $\sin 90^\circ = +1$, $\sin 180^\circ = +0$, $\sin 270^\circ = -1$, $\sin 360^\circ = -0$; $\cos 0^\circ = +1$, $\cos 90^\circ = +0$; $\cos 180^\circ = -1$, $\cos 270^\circ = -0$, $\cos 360^\circ = +1$. Substituting these results in the formulas of *Art.* 36, we have the following

TABLE.

ARC.	SIN.	COS.	TAN.	COT.	SEC.	COSEC.
0°	+0	+1	+0	$+\infty$	+1	$+\infty$
90°	+1	+0	$+\infty$	+0	$+\infty$	+1
180°	+0	-1	-0	$-\infty$	-1	$+\infty$
270°	-1	-0	$+\infty$	+0	$-\infty$	-1
360°	-0	+1	-0	$-\infty$	+1	$-\infty$

Functions of Certain Angles.

40. 1°. Let $F'AF$ be an arc of 60° , and let CA be drawn perpendicular to the chord $F'B$; then AF will be an arc of 30° , HF will be the sine of 30° , and CH will be the cosine of 30° .

The chord FF' is equal to 1; consequently, HF is equal to $\frac{1}{2}$; that is, $\sin 30^\circ = \frac{1}{2}$. From formula (1), *Art.* 36, we have,

$$\cos 30^\circ = \sqrt{1 - \frac{1}{4}} = \frac{1}{2}\sqrt{3}.$$

2°. Let AF be an arc of 45° ; HF is its sine, and CH its cosine.

Then, because ACF is equal to 45° , HFC is also equal to 45° , and consequently, CH is equal to HF . But, $\overline{CH}^2 + \overline{HF}^2 = \overline{CF}^2$, or $2\overline{CH}^2 = \overline{CF}^2$, or, $2 \sin^2 45^\circ = 1$; hence,

$$\sin 45^\circ = \sqrt{\frac{1}{2}} = \frac{1}{2}\sqrt{2}, \text{ and } \cos 45^\circ = \sqrt{\frac{1}{2}} = \frac{1}{2}\sqrt{2}.$$

From formulas (2) and (4), *Art.* 36, we have,

$$\tan 45^\circ = 1, \text{ and } \cot 45^\circ = 1.$$

3°. Because the sine of an arc is equal to the cosine of its complement, and the reverse, we have, from principle 1°,

$$\sin 60^\circ = \frac{1}{2}\sqrt{3} \text{ and } \cos 60^\circ = \frac{1}{2},$$

Functions of the Sum and Difference of Two Arcs.

41. Let AF and FG be two arcs of the trigonometric circle; denote the former by x , and the latter by y .

Draw the radii CA , CF , and CG ; from G draw GK perpendicular to CF , and GH perpendicular to CA ; from K , draw KM perpendicular to CA , and KL parallel to CA ; then, HG will be the sine of $x + y$, CH the cosine of $x + y$, KG the sine of y , and CK the cosine of y .

From the figure, we have,

$$HG = HL + LG, \text{ or, } \sin(x + y) = LG + HL. \quad (1)$$

Now, the triangle KLK is similar to the triangle KMC , (*P.* 15, *Cor.* 2, *B.* 3); hence, the angle KGL is equal to x . From the right-angled triangle KLK , we have, (*Art.* 29),

$$LG = KG \cos x = \cos x \sin y,$$

and from the right-angled triangle CMK , we have,

$$HL = MK = CK \sin x = \sin x \cos y.$$

Substituting these values in (1), we have,

$$\sin(x + y) = \sin x \cos y + \cos x \sin y. \quad (a)$$

Formula (a) is true for all values of x and y ; if we therefore substitute $-y$ for y and reduce, (*Art.* 38), we have,

$$\sin (x-y)=\sin x \cos y-\cos x \sin y . . . (b)$$

If we substitute $90^{\circ}-x$, for x , in (b), we have,

$$\sin \left[90^{\circ}-(x+y)\right]=\sin \left(90^{\circ}-x\right) \cos y-\cos \left(90^{\circ}-x\right) \sin y ; \quad (2)$$

but, the sine of 90° *minus* an arc, is equal to the cosine of the arc, and the cosine of 90° *minus* an arc, is equal to the sine of the arc; hence, equation (2) becomes

$$\cos (x+y)=\cos x \cos y-\sin x \sin y . . . (c)$$

If we substitute $-y$, for y , in (c), and reduce (*Art.* 38), we have,

$$\cos (x-y)=\cos x \cos y+\sin x \sin y . . . (d)$$

If we divide (a) by (c), member by member, we have,

$$\frac{\sin (x+y)}{\cos (x+y)}=\frac{\sin x \cos y+\cos x \sin y}{\cos x \cos y-\sin x \sin y} ;$$

dividing both terms of the second member by $\cos x \cos y$ and reducing, by the principle that the sine, divided by the cosine, is equal to the tangent, we have,

$$\tan (x+y)=\frac{\tan x+\tan y}{1-\tan x \tan y} (e)$$

If we substitute $-y$, for y , in (e), and reduce, (*Art.* 38), we have,

$$\tan (x-y)=\frac{\tan x-\tan y}{1+\tan x \tan y} (f)$$

Functions of Double Arcs.

42. If we make $y = x$ in the formulas (a), (c), and (e) of Art. 41, and reduce, we have,

$$\sin 2x = 2 \sin x \cos x \quad . \quad . \quad . \quad . \quad . \quad (a')$$

$$\cos 2x = \cos^2 x - \sin^2 x \quad . \quad . \quad . \quad . \quad . \quad (c')$$

$$\tan 2x = \frac{2 \tan x}{1 - \tan^2 x} \quad . \quad . \quad . \quad . \quad . \quad (e')$$

If we substitute $1 - \sin^2 x$, for $\cos^2 x$, in (c'), and then substitute $1 - \cos^2 x$, for $\sin^2 x$, and reduce, we have,

$$\cos 2x = 1 - 2 \sin^2 x, \text{ or, } \sin x = \sqrt{\frac{1}{2}(1 - \cos 2x)}, \quad . \quad . \quad (k)$$

$$\cos 2x = 2 \cos^2 x - 1, \text{ or, } \cos x = \sqrt{\frac{1}{2}(1 + \cos 2x)}, \quad . \quad . \quad (l)$$

Additional Formulas.

43. If we add (b) to (a), member to member, and then subtract (b) from (a), member from member, we have,

$$\sin (x + y) + \sin (x - y) = 2 \sin x \cos y; \quad . \quad . \quad (1)$$

$$\sin (x + y) - \sin (x - y) = 2 \cos x \sin y. \quad . \quad . \quad (2)$$

In like manner, we deduce from formulas (d) and (c),

$$\cos (x + y) + \cos (x - y) = 2 \cos x \cos y; \quad . \quad . \quad (3)$$

$$\cos (x - y) - \cos (x + y) = 2 \sin x \sin y. \quad . \quad . \quad (4)$$

If we now make

$$x = \frac{1}{2}(p + q), \text{ and, } y = \frac{1}{2}(p - q),$$

or, $x + y = p$ and $x - y = q,$

we have from formulas (1), (2), (3), and (4),

$$\sin p + \sin q = 2 \sin \frac{1}{2}(p + q) \cos \frac{1}{2}(p - q); \dots (m)$$

$$\sin p - \sin q = 2 \cos \frac{1}{2}(p + q) \sin \frac{1}{2}(p - q); \dots (n)$$

$$\cos p + \cos q = 2 \cos \frac{1}{2}(p + q) \cos \frac{1}{2}(p - q); \dots (o)$$

$$\cos q - \cos p = 2 \sin \frac{1}{2}(p + q) \sin \frac{1}{2}(p - q); \dots (p)$$

Dividing (p) by (o), member by member, remembering that the *sine*, divided by the *cosine*, is equal to the *tangent*, we have,

$$\frac{\cos q - \cos p}{\cos q + \cos p} = \tan \frac{1}{2}(p + q) \tan \frac{1}{2}(p - q). \dots (q)$$

If we substitute $\frac{1}{2}x$, for x , in (k) and (l), and reduce, we have,

$$\sin \frac{1}{2}x = \sqrt{\frac{1}{2}(1 - \cos x)}, \text{ or, } 1 - \cos x = 2 \sin^2 \frac{1}{2}x. \dots (r)$$

$$\cos \frac{1}{2}x = \sqrt{\frac{1}{2}(1 + \cos x)}, \text{ or, } 1 + \cos x = 2 \cos^2 \frac{1}{2}x. \dots (s)$$

Functions of Arcs Greater than 90° .

44. Every arc greater than 90° is made up of one or more quadrants, plus or minus an arc less than 90° . Denote this auxiliary arc by z .

If we take an arc in the second quadrant it may be denoted by $90^\circ + z$, or by $180^\circ - z$, an arc in the third quadrant may be denoted by $180^\circ + z$ or by $270^\circ - z$, and an arc in the fourth quadrant may be denoted by $270^\circ + z$, or by $360^\circ - z$.

The functions of these arcs can be found in terms of z by formulas (a), (b), (c), &c., as follows:

$$\sin (90^\circ + z) = \sin 90^\circ \cos z + \sin z \cos 90^\circ = \cos z,$$

$$\sin (180^\circ - z) = \sin 180^\circ \cos z - \sin z \cos 180^\circ = + \sin z, \text{ \&c.}$$

By proceeding in this manner we may form the following

TABLE.

$Arc = 90^\circ + z.$ $\sin = \cos z, \quad \cos = -\sin z.$ $\tan = -\cot z, \quad \cot = -\tan z.$	$Arc = 270^\circ - z.$ $\sin = -\cos z, \quad \cos = -\sin z,$ $\tan = \cot z, \quad \cot = \tan z.$
$Arc = 180^\circ - z,$ $\sin = \sin z, \quad \cos = -\cos z.$ $\tan = -\tan z, \quad \cot = -\cot z.$	$Arc = 270^\circ + z.$ $\sin = -\cos z, \quad \cos = \sin z.$ $\tan = -\cot z, \quad \cot = -\tan z.$
$Arc = 180^\circ + z.$ $\sin = -\sin z, \quad \cos = -\cos z,$ $\tan = \tan z, \quad \cot = \cot z.$	$Arc = 360^\circ - z.$ $\sin = -\sin z, \quad \cos = \cos z.$ $\tan = -\tan z, \quad \cot = -\cot z.$

V. SPHERICAL TRIGONOMETRY.

Definition and Explanations.

45. Spherical Trigonometry is that branch of Trigonometry which treats of the solution of Spherical Triangles.

In every spherical triangle there are six *parts*, three sides and three angles. If any three of these parts are given, the others can be found by computation.

The method of solving spherical triangles is entirely similar to that explained in *Art.* 28. In applying this method, we shall suppose that all the triangles considered lie on the surface of a sphere whose radius is equal to 1; we shall also suppose that each part of every triangle is less than 180° .

Formulas, used in Solving Right-angled Spherical Triangles.

46. Let ACD be a spherical triangle, right-angled at A, and let O be the centre of the sphere on which it is situated.

Draw the radii OA, OC, and OD; from D, draw DH perpendicular to OA and from H, draw HE perpen-

dicular to OC; then draw ED. The line ED is perpendicular to OC, (P. 5, B. 6), and consequently, the angle HED is equal to the dihedral angle whose edge is OC, (*Art. 92, Geom.*), that is, it is equal to the spherical angle ACD. Because A is a right angle, the planes OAC and OAD are perpendicular to each other; hence, DH is perpendicular to the plane AOC, (P. 14, *Cor. 1, B. 6*), and consequently, to the line HE; that is, the triangle EHD is right-angled at H.

Denote the angles of the triangle by A, D, and C, and the sides opposite these angles by a , d , and c . Then, is HD equal to $\sin c$, OH, to $\cos c$, ED, to $\sin a$, and OE, to $\cos a$.

It is to be observed, that we may interchange C and D, provided we also interchange c and d .

From the right-angled triangle EHD, we have,

$$DH = ED \sin HED,$$

$$\text{or,} \quad \sin c = \sin a \sin C; \quad . \quad . \quad . \quad . \quad . \quad (1)$$

changing c into d , and C into D, we have,

$$\sin d = \sin a \sin D. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

From the right-angled triangle OEH, we have,

$$OE = OH \cos EOH,$$

$$\text{or,} \quad \cos a = \cos c \cos d. \quad . \quad . \quad . \quad . \quad . \quad (3)$$

From the triangles EHD and OEH, we have,

$$\cos HED = \frac{EH}{ED} = \frac{OH \sin EOH}{ED},$$

or,
$$\cos C = \frac{\cos c \sin d}{\sin a};$$

substituting for $\sin d$, its value taken (2) and reducing, we have,

$$\cos C = \cos c \sin D; \quad . \quad . \quad . \quad . \quad . \quad (4)$$

changing C into D , c into d , and D into C , we have,

$$\cos D = \cos d \sin C. \quad . \quad . \quad . \quad . \quad . \quad (5)$$

From the same triangles as before, we have,

$$\tan HED = \frac{HD}{EH} = \frac{HD}{OH \sin EOH},$$

or,
$$\tan C = \frac{\sin c}{\cos c \sin d} = \frac{\tan c}{\sin d},$$

whence, by reduction, remembering that the cotangent is equal to the reciprocal of the tangent, we have,

$$\sin d = \tan c \cot C; \quad . \quad . \quad . \quad . \quad . \quad (6)$$

changing d into c , c into d , and C into D , we have,

$$\sin c = \tan d \cot D. \quad . \quad . \quad . \quad . \quad . \quad (7)$$

From the same triangles as before, we have,

$$\cos HED = \frac{EH}{ED} = \frac{OE \tan EOH}{ED},$$

or,
$$\cos C = \frac{\cos a \tan d}{\sin a} = \cot a \tan d, \quad . \quad . \quad . \quad (8)$$

changing C into D , and d into c , we have,

$$\cos D = \cot a \tan c. \quad . \quad . \quad . \quad . \quad . \quad (9)$$

Multiplying (7) by (6), member by member, we have,

$$\sin c \sin d = \tan c \tan d \cot C \cot D ;$$

dividing both members by $\tan c \tan d$, remembering that the sine divided by the tangent is equal to the cosine, we have,

$$\cos c \cos d = \cot C \cot D ;$$

substituting for $\cos c \cos d$, its value taken from (3), we have,

$$\cos a = \cot C \cot D (10)$$

Formulas (1) to (10) enable us to solve a right-angled spherical triangle, when any two parts besides the right angle are given.

Napier's Rules for circular parts.

47. In any right-angled triangle, the two sides about the right angle, the complements of the opposite angles, and the complement of the hypotenuse, are called **Napier's circular parts**.

Let these parts, taken in order, be arranged in a circle, as shown in the diagram. If we take any three of these parts, they will either be adjacent to each other, or one of them will be separated from each of the other two by an intervening part. In the former case, the one lying between the other two, is called the **middle part**, and the other two, are called **adjacent parts**; in the latter case the one that is separated from the other two is called the **middle part**, and the other two are called **opposite parts**. Now let us take each part in succession as a middle part, first regarding only the *opposite parts*, and then regarding only the *adjacent parts*.

1°. From formulas (1), (2), (4), (3), and (5), of *Art.* 46, we have, after a slight change of form,

$$\sin c = \cos (90^\circ - a) \cos (90^\circ - C); \quad (1)$$

$$\sin d = \cos (90^\circ - a) \cos (90^\circ - D); \quad (2)$$

$$\sin (90^\circ - C) = \cos c \cos (90^\circ - D); \quad . . . \quad (3)$$

$$\sin (90^\circ - a) = \cos c \cos d; \quad \quad (4)$$

$$\sin (90^\circ - D) = \cos d \cos (90^\circ - C). \quad . . . \quad (5)$$

. Comparing these formulas with the diagram, we see that the following rule is always true :

1st. *The sine of the middle part is equal to the rectangle of the cosine of the opposite parts.*

2°. From formulas (7), (6), (8), (10), and (9), of *Art.* 46, we have,

$$\sin c = \tan d \tan (90^\circ - D); \quad . . . \quad (6)$$

$$\sin d = \tan c \tan (90^\circ - C); \quad . . . \quad (7)$$

$$\sin (90^\circ - C) = \tan (90^\circ - a) \tan d; \quad . . . \quad (8)$$

$$\sin (90^\circ - a) = \tan (90^\circ - C) \tan (90^\circ - D); \quad (9)$$

$$\sin (90^\circ - D) = \tan (90^\circ - a) \tan c. \quad . . . \quad (10)$$

Comparing these formulas with the diagram, we see that the following rule is always true :

2d. *The sine of the middle part is equal to the rectangle of the tangents of the adjacent parts.*

Discussion.

48. In applying Napier's rules, the required part is always determined by means of its sine. Now, the same sine corresponds to two different arcs, which are supplements of each other; it is, therefore, important to ascertain which of these is to be taken.

Two arcs, or angles, are said to be of the **same species**, when both are less than 90° , or both greater than 90° ;

they are of different species, when one is greater, and the other less than 90° .

From formula (4), Art. 46, we have,

$$\sin D = \frac{\cos C}{\cos c} (1)$$

Now, the first member of (1) is always positive, because D is always less than 180° ; consequently, $\cos C$ must have the same sign as $\cos c$; this can only be the case when C and c are of the same species; hence, we have the following principle:

1°. *Each side about the right angle must be of the same species as its opposite angle.*

Formula (3), Art. 46, is

$$\cos a = \cos d \cos c (2)$$

If a is less than 90° , $\cos a$ is positive; consequently $\cos d$ and $\cos c$ must have the same sign, that is, d and c must be of the same species; if a is greater than 90° , $\cos a$ is negative; consequently, $\cos d$ and $\cos c$ must have contrary signs, that is, d and c must be of different species; hence, the following principle:

2°. *If the hypotenuse is less than 90° , the sides about the right angle must be of the same species; if the hypotenuse is greater than 90° , the sides about the right angle must be of different species.*

These principles enable us to decide as to the value of the arc, or angle, in every instance, except when we have given an oblique angle and its opposite side. Then, there may be several cases.

Let ACD be right-angled at A , and let the angle C , and the side DA be given. Prolong CD and CA till they intersect at C' . Lay off $C'D'$

equal to CD , $C'A'$ equal to CA , and draw the arc $A'D'$. The triangles ACD and $A'C'D'$ have two sides and their included angle equal, each to each; hence, the remaining parts are equal, each to each, that is, the angle A' is equal to A , the angle D' to D , and the side $D'A'$ to DA . The triangles ACD and $A'CD'$ have, therefore, the angle C common, and the opposite sides AD and $A'D'$ equal; consequently, whenever the triangle $A'CD'$ can be formed, there are two solutions. But in order that this triangle may be formed, the given parts must satisfy equation (4), *Art.* 46, which gives,

$$\sin D = \frac{\cos C}{\cos c}, \dots \dots \dots (3)$$

in which $\sin D$ cannot be greater than 1, nor less than 0.

First. Let C and c be of the same species, and let the difference between C and 90° be *less* than the difference between c and 90° . In this case, $\cos C$ is *numerically less* than $\cos c$; condition (3) is satisfied; and there are *two* solutions.

Secondly. Let C be equal to c . In this case, $\sin D$ is equal to 1, that is, D is equal to 90° ; the two triangles ACD and $A'CD'$, are bi-rectangular and equal; and there is but *one* solution.

Thirdly. Let C and c be of the same species, and let the difference between C and 90° be greater than the difference between c and 90° . In this case, $\cos C$ is *numerically greater*

than $\cos c$; condition (3) is not satisfied; and there is no solution.

Fourthly. Let C and c be of different species. In this case $\cos C$ and $\cos c$ have different signs; condition (3) is not satisfied; and there is no solution.

Applications of Napier's Rules.

49. In applying Napier's rules, two of the circular parts must be given. Then, whatever these may be, we select that formula of *Art.* 47, whose second member contains the given parts, and by means of this formula we find a third part. In like manner, we find each of the other parts in succession.

It is to be observed that we can find any one of the unknown parts, without finding the others. To this end, we select the formula which contains the required and the given parts, and, if necessary, solve it with respect to the required part. From this, we find the numerical value of the required part by means of logarithms.

Note.—In solving the following examples, let seconds of arcs be neglected at every step of the operation. In taking out arcs corresponding to logarithmic functions, stop at the one next lower than the given logarithm.

EXAMPLES.

1. Given, $a = 86^\circ 51'$ and $d = 18^\circ 2'$, to find the remaining parts.

OPERATION.

Applying logarithms to formula (8), *Art.* 47, we have,

$$\log \sin (90^\circ - C) = \log \tan (90^\circ - a) + \log \tan d - 10;$$

substituting the proper values of a and d , we have,

$$\log \tan 3^\circ 9' . . 8.740626$$

$$\log \tan 18^\circ 2' . . \underline{9.512635}$$

$$\therefore C = 90^\circ - \log \sin^{-1} 8.253261 = 90^\circ - 1^\circ 1' = 88^\circ 59'.$$

Applying logarithms to formula (5), *Art.* 47, we have,

$$\log \sin (90^\circ - D) = \log \cos d + \log \cos (90^\circ - C) - 10;$$

$$\log \cos 18^\circ 2' . . 9.978124$$

$$\log \cos 1^\circ 1' . . \underline{9.999932}$$

$$\therefore D = 90^\circ - \log \sin^{-1} 9.978056 = 90^\circ - 71^\circ 56' = 18^\circ 4'.$$

Applying logarithms to formula (1), *Art.* 47, we have,

$$\log \sin c = \log \cos (90^\circ - a) + \log \cos (90^\circ - C) - 10,$$

or, $\log \sin c = \log \sin a + \log \sin C - 10;$

$$\log \sin 86^\circ 51' . . 9.999343$$

$$\log \sin 88^\circ 59' . . \underline{9.999932}$$

$$\therefore c = \log \sin^{-1} 9.999275 = 86^\circ 41'.$$

2. Given, $a = 142^\circ 9'$, and $C = 54^\circ 1'$, to find the remaining parts.

In this example, we use formulas (1), (7), and (9), which give the logarithmic formulas

$$\log \sin c = \log \sin a + \log \sin C - 10, . . (a)$$

$$\log \sin d = \log \tan c + \log \cot C - 10, . . (b)$$

$$\log \cos D = \log \cot a + \log \tan c - 10. . . (c)$$

From (a), (b), and (c), we find,

$$c = 29^\circ 46', \quad d = 155^\circ 28', \quad \text{and } D = 137^\circ 23'. \text{ Ans.}$$

NOTE.—The side c must be less than 90° , (*Prin.* 1°, *Art.* 48); and because a is greater than 90° , c and d must be of different species, (*Prin.* 2°, *Art.* 48); from *Prin.* 1°, *Art.* 48, D and d must be of the same species.

3. Given, $c = 115^\circ 20'$, and $C = 91^\circ 2'$, to find the remaining parts.

$$d = \begin{cases} 2^\circ 11', \\ 177^\circ 49', \end{cases} \quad D = \begin{cases} 2^\circ 24', \\ 177^\circ 36', \end{cases} \quad a = \begin{cases} 115^\circ 19', \\ 64^\circ 41'. \end{cases} \text{ Ans.}$$

NOTE.—Because the difference between C and 90° , is less than the difference between c and 90° , there are two solutions, (*Art.* 48).

4. Given, $a = 78^\circ 20'$, and $C = 37^\circ 25'$, to find d .

Applying logarithms to formula (8), *Art.* 47, we have,

$$\log \cos C = \log \cot a + \log \tan d - 10;$$

whence, $\log \tan d = \log \cos C + (10 - \log \cot a)$,

$$\text{or,} \quad \log \tan d = \log \cos C + (a \cdot c) \log \cot a. \quad \dots (1)$$

From (1) we find, $d = 75^\circ 25'$.

Solution of Quadrantal Triangles.

50. We may solve a quadrantal triangle, that is, a triangle in which one side is a quadrant, by finding its polar triangle, which will be a right-angled spherical triangle; this triangle

may be solved by Napier's rules, *Art.* 47; then, by passing back to *its* polar triangle, we shall have the parts of the given quadrantal triangle.

Formulas used in solving oblique spherical triangles.

51. In what follows, the angles of a spherical triangle will be denoted by A , C , and D ; and their opposite sides by a , c , and d .

First. From the vertex D , of the spherical triangle ACD , draw the arc DE , perpendicular to the side AC , and denote it by p .

From formula (1), *Art.* 46, we have,

$$\sin p = \sin c \sin A, \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and,

$$\sin p = \sin a \sin C. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Equating the second members of (1) and (2), we have,

$$\sin c \sin A = \sin a \sin C,$$

or,

$$\sin a : \sin c :: \sin A : \sin C. \quad . \quad . \quad . \quad . \quad (3)$$

Hence, we have the following principle:

1°. In any spherical triangle, the sines of any two sides, are to each other, as the sines of their opposite angles.

NOTE.—If the point E falls on the prolongation of CA , the preceding formulas, and their consequent principle, will hold true.

Secondly. If we denote the distances from E to A , and

from E to C respectively, by s' and s , we have from formula (3), *Art.* 46,

$$\cos c = \cos p \cos s', \text{ and } \cos a = \cos p \cos s,$$

whence, the proportion,

$$\cos c : \cos a :: \cos s' : \cos s; \quad . \quad . \quad . \quad (4)$$

from which, by composition and division, we have,

$$\cos c + \cos a : \cos c - \cos a :: \cos s' + \cos s : \cos s' - \cos s,$$

$$\text{or,} \quad \frac{\cos c - \cos a}{\cos c + \cos a} = \frac{\cos s' - \cos s}{\cos s' + \cos s} \quad . \quad . \quad . \quad (5)$$

Substituting for each member of (5), its value taken from formula (q), *Art.* 43, we have,

$$\tan \frac{1}{2}(a + c) \tan \frac{1}{2}(a - c) = \tan \frac{1}{2}(s + s') \tan \frac{1}{2}(s - s');$$

or,

$$\tan \frac{1}{2}(a + c) : \tan \frac{1}{2}(s + s') :: \tan \frac{1}{2}(s - s') : \tan \frac{1}{2}(a - c). \quad . \quad (6)$$

Hence, the following principle:

2°. *If a perpendicular is drawn from the vertex of any angle of a spherical triangle, the tangent of half the sum of the including sides, is to the tangent of half the sum of the segments of the other side, as the tangent of half the difference of the segments is to the tangent of half the difference of the including sides.*

NOTE.—If the point E falls on the prolongation of CA, the segments EA and EC are called *external* segments; in this case, the segment EA is to be regarded as *negative*. With this understanding, the preceding formulas, and their consequent principle, will hold true.

Solution of oblique spherical triangles.

52. Every spherical triangle contains *six* parts, *three* sides and *three* angles; if any three of these parts are given, the other three may be found by computation. There may be three cases.

FIRST CASE. *Given, two sides and an angle opposite one of them, to find the remaining parts. Or, given, two angles and a side opposite one, to find the other parts.*

1°. Let the sides a , c , and the angle C , be given. The remaining parts can then be found by means of the formulas of *Arts.* 47 and 51.

The angle A is determined by means of its sine; and because the sine of an angle is equal to the sine of its supplement, it may happen that there will be two solutions. To ascertain when there will be two solutions, let the arcs CD and CA be prolonged till they meet at C' . Lay off EA' equal to EA , and draw the arc DA' . The right-angled triangles AED and $A'ED$, have two sides and the included angle of the one, equal to two sides and the included angle of the other, each to each; hence, they are equal in all their parts; therefore, the angle $EA'D$ is equal to EAD , and the side DA' to DA . But, the sine of $CA'D$ is equal to the sine of its supplement $EA'D$; hence, the sines of a , c , A , and C belong equally to the two triangles ACD and $A'CD$. There will, therefore, be two solutions whenever these two triangles can be formed; that is, when both A and A' fall between C and C' . Hence, if $s - s' > 0^\circ$, that is, if $s > s'$, and if $s + s' < 180^\circ$, there will be *two* solutions.

If $s - s' < 0^\circ$, that is, if $s < s'$, and if $s + s' < 180^\circ$, it is obvious that there will be but *one* solution. If $s' = 0$, $\triangle ACD$ and $\triangle A'CD$ will coincide and there will be but *one* solution.

From formula (1), *Art.* 46, we have,

$$\sin p = \sin c \sin A, \text{ or } \sin A = \frac{\sin p}{\sin c}. \quad . \quad . \quad (1)$$

If $\sin p > \sin c$, equation (1) will not be satisfied, and there will be *no* solution.

EXAMPLES.

1. Given, $a = 72^\circ 10'$, $c = 79^\circ$, and $C = 32^\circ 20'$; to find the remaining parts.

We first find s and s' .

From the right-angled triangle CED , we have,

$$\sin(90^\circ - C) = \tan(90^\circ - a) \tan s, \quad . \quad (2)$$

from which we deduce the logarithmic formula,

$$\log \tan s = \log \cos C + \log \tan a - 10.$$

$$\log \cos 32^\circ 20' \quad . \quad . \quad 9.926831$$

$$\log \tan 72^\circ 10' \quad . \quad . \quad 10.492540$$

$$s = \log \tan^{-1} 10.419371 = 69^\circ 9'.$$

Because $\sin(90^\circ - C)$, and $\tan(90^\circ - a)$, are positive in (2), $\tan s$ must be positive; hence, s is less than 90° .

Applying logarithms to proportion (4), *Art.* 51, we have,

$$\log \cos s' = \log \cos c + \log \cos s + (a \cdot c) \log \cos a - 10.$$

$$\begin{array}{rcl} \log \cos 79^\circ & . & . & . & 9.280599 \\ \log \cos 69^\circ 9' & . & . & . & 9.551356 \\ (a \cdot c) \log \cos 72^\circ 10' & . & . & . & \underline{0.513925} \\ s' = \log \cos^{-1} 9.345880 & = & 77^\circ 13'. \end{array}$$

Because the first, second, and fourth terms of proportion (4), *Art.* 51, are positive, the third term is positive; hence, s' is less than 90° .

We see that $s < s'$, and that $s + s' < 180^\circ$; hence, there is but one solution.

Applying logarithms to proportion (3), *Art.* 51, we have,

$$\log \sin A = \log \sin a + \log \sin C + (a \cdot c) \log \sin c - 10.$$

From this formula, we have,

$$\begin{array}{rcl} \log \sin 72^\circ 10' & . & . & 9.978615 \\ \log \sin 32^\circ 20' & . & . & 9.728227 \\ (a \cdot c) \log \sin 79^\circ & . & . & . & \underline{0.008053} \\ \therefore A = \log \sin^{-1} 9.714895 & = & 31^\circ 14'. \end{array}$$

Because $C < 90^\circ$, it is obvious that p is less than 90° ; but p and A are of the same species; hence, we take the acute value of A .

The side AC is equal to $s + s'$; hence, $d = 146^\circ 22'$.

From Napier's rules, we have,

$$\text{and,} \quad \log \cos EDC = \log \sin C + \log \cos s - 10,$$

$$\log \cos EDA = \log \sin A + \log \cos s' - 10,$$

From the first of these, we find $EDC = 79^\circ 2'$, and from the second, we find $EDA = 83^\circ 24'$. Hence,

$$CDA = EDC + EDA = 162^\circ 26'.$$

2°. Let A , C , and c , be given; to find the remaining parts.

If we subtract each of the given parts from 180° , we shall have two sides and an angle opposite one of them, in the polar triangle; we can solve the polar triangle in the manner just explained, and then by subtracting each of the parts found, from 180° , we have the required parts of the given triangle.

EXAMPLE.

1. Given, $A = 58^\circ 8'$, $C = 50^\circ 12'$, and $c = 62^\circ 42'$, to find the remaining parts.

Subtracting A , C , and c , from 180° and denoting the results by a' , c' , and C' , we have in the polar triangle $a' = 121^\circ 52'$, $c' = 129^\circ 48'$, and $C' = 117^\circ 18'$, to find the remaining parts.

The polar triangle has two solutions giving

$$A' = \begin{cases} 100^\circ 48' \\ 79^\circ 12' \end{cases}; \quad D' = \begin{cases} 60^\circ 56' \\ 27^\circ 46' \end{cases}; \quad d' = \begin{cases} 49^\circ 5' \\ 23^\circ 45' \end{cases}.$$

Passing to the given triangle by subtracting each of these parts from 180° , we have,

$$a = \begin{cases} 79^\circ 12' \\ 100^\circ 48' \end{cases}; \quad d = \begin{cases} 119^\circ 4' \\ 152^\circ 14' \end{cases}; \quad D = \begin{cases} 130^\circ 55' \\ 156^\circ 15' \end{cases}. \text{ Ans.}$$

SECOND CASE. *Given, two sides and their included angle, to find the remaining parts. Or, given, two angles and their included side, to find the remaining parts.*

1°. Let the sides a , d , and the included angle C , be given, to find the other parts.

We first find the perpendicular p , and the segments s and s' ; we then complete the solution by Napier's rules.

EXAMPLES.

1. Given, $a = 68^\circ 46'$, $d = 37^\circ 10'$, and $C = 39^\circ 23'$, to find the remaining parts.

From the right-angled triangle CED, we have,

$$\log \sin p = \log \sin C + \log \sin a - 10,$$

and, $\log \sin s = \log \tan p + \log \cot C - 10.$

From these formulas we find,

$$p = 36^\circ 15', \text{ and } s = 63^\circ 16'.$$

Because s is greater than d , the segments are external, and s' is therefore equal to $d - s$, or to $-26^\circ 6'$.

From the right-angled triangles CED and AED, we have,

$$\cos c = \cos p \cos s'; \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$\cos A = \tan s' \cot c; \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$\cos EDC = \tan p \cot a; \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$\cos EDA = \tan p \cot c. \quad . \quad . \quad . \quad . \quad . \quad (4)$$

From these formulas, by means of logarithms, we find,

$$c = 43^\circ 36', \quad A = 120^\circ 57', \quad EDC = 73^\circ 27', \quad \text{and} \\ EDA = 39^\circ 39'.$$

Because s' is negative, $\tan s'$ is negative in (2), and consequently $\cos A$ is negative; hence, A is greater than 90° .

Because s and s' are external segments, the angle D is equal to $EDC - EDA$; hence,

$$D = 73^\circ 27' - 39^\circ 39' = 33^\circ 48'.$$

2°. Let the angles A , D , and the included side c , be given, to find the other parts.

We pass to the polar triangle as before; we then solve the polar triangle, as just explained; we next pass back to the given triangle, which will then be completely known.

EXAMPLES.

1. Given, $A = 51^\circ 30'$, $D = 131^\circ 30'$, and $c = 80^\circ 19'$; to find the remaining parts.

Ans. $C = 59^\circ 16'$, $a = 63^\circ 50'$, and $d = 120^\circ 46'$.

2. Given, $A = 34^\circ 15'$, $D = 42^\circ 15'$, and $c = 76^\circ 37'$; to find the remaining parts.

Ans. $a = 40^\circ 3'$, $d = 50^\circ 6'$, and $C = 121^\circ 37'$.

THIRD CASE. *Given, the three sides, to find the three angles. Or, given, the three angles, to find the three sides.*

We find the half difference of s and s' by formula (6), *Art.* 51; we then add the half difference to $\frac{1}{2}(s+s')$, or $\frac{1}{2}d$, to find the greater segment, and subtract the half difference from $\frac{1}{2}d$ to find the less segment; the solution is then completed as in previous cases.

EXAMPLE.

1. Given, $a = 83^\circ 14'$, $c = 56^\circ 40'$, and $d = 114^\circ 30'$; to find A, C, and D.

Applying logarithms to formula (6), *Art.* 51, remembering that $s + s'$ is equal to d , we have,

$$\log \tan \frac{1}{2}(s - s') = \log \tan \frac{1}{2}(a + c) + \log \tan \frac{1}{2}(a - c) - \log \tan \frac{1}{2}d.$$

$$\log \tan 69^\circ 57' \quad . \quad . \quad . \quad 10.437756$$

$$\log \tan 13^\circ 17' \quad . \quad . \quad . \quad 9.373064$$

$$\hline 19.810820$$

$$\log \tan 57^\circ 15' \quad . \quad . \quad . \quad 10.191639$$

$$\frac{1}{2}(s - s') = \log \tan^{-1} 9.619181 = 22^\circ 35'.$$

$$\therefore s = \frac{1}{2}(s + s') + \frac{1}{2}(s - s') = 57^\circ 15' + 22^\circ 35' = 79^\circ 50'.$$

$$s' = \frac{1}{2}(s + s') - \frac{1}{2}(s - s') = 57^\circ 15' - 22^\circ 35' = 34^\circ 40'.$$

From the right-angled triangles CED and AED, we have,

$$\cos C = \tan s \cot a; \quad . \quad . \quad . \quad (1)$$

$$\cos A = \tan s' \cot c; \quad . \quad . \quad . \quad (2)$$

$$\cos EDA = \sin A \cos s'; \quad . \quad . \quad . \quad (3)$$

$$\cos EDC = \sin C \cos s. \quad . \quad . \quad . \quad (4)$$

From these formulas, by the aid of logarithms, we find,

$$C = 48^\circ 35', \quad A = 62^\circ 57', \quad EDA = 42^\circ 55', \quad \text{and} \quad EDC = 82^\circ 24';$$

$$\text{hence, } D = EDA + EDC = 125^\circ 19'.$$

2°. Let the angles A, C, and D, be given, to find the sides a , c , and d .

If we subtract each of the given angles from 180° , we have the corresponding sides of a polar triangle, which can be solved by the method just explained. If we then subtract each angle of this triangle from 180° , we have the sides of the primitive triangle.

EXAMPLE.

1. Given, $A = 48^\circ 30'$, $C = 62^\circ 54'$, and $D = 125^\circ 20'$, to find the remaining parts.

Ans. $a = 56^\circ 41'$, $c = 83^\circ 12'$, and $d = 114^\circ 30'$.

MENSURATION.

INTRODUCTION.

Definitions.

1. The **measure** of a quantity is an expression for the quantity in terms of a quantity of the same kind taken as a *unit*.

2. **Mensuration** is that branch of mathematics which treats of the measurement of Geometrical magnitudes.

The rules of Mensuration are simple deductions from the principles and formulas of Geometry.

Explanatory remarks.

3. The **unit of measure of any line** is a straight line ; as 1 foot, 1 yard, &c. The measure of the line is a denominate number, whose unit is the assumed *linear unit*.

4. The **unit of measure of a surface** is a square, one of whose sides is the linear unit ; as 1 square foot, 1 square yard, &c. The measure of a surface is a denominate number, whose unit is the assumed *superficial unit*.

By the **product of two lines**, we mean the product obtained by multiplying the number of linear units in one,

by the number of linear units in the other. The unit of the product is a *superficial unit*.

5. The unit of measure of a volume is a cube, one of whose edges is the linear unit; as, 1 cubic foot, 1 cubic yard, &c. The measure or content of a volume is a denominate number, whose unit is the assumed *cubic unit*.

By the product of three lines, we mean the continued product of the number of linear units in each line. The unit of the product is a *cubic unit*, or a *unit of volume*.

By the product of a line and a surface, we mean the product obtained by multiplying the number of linear units in the line, by the number of superficial units in the surface. The unit of the product is a *cubic unit*, or a *unit of volume*.

Note.—In what follows, the results are only approximate; as a general rule, numbers will be carried out to two places of decimals and angles to minutes of arc; the last figure in either case will generally be of doubtful value.

I. MENSURATION OF LINES.

Lines considered.

6. The only lines treated of in Elementary Geometry are straight lines, and arcs of circles.

1°. To find the hypotenuse of a right-angled triangle.

RULE.

Find the sum of the squares of the sides about the right angle and extract the square root of the result, (P. 8, B. 4.)

EXAMPLES.

1. The sides about a right angle are 400 yds., and 600 yds.; what is the length of the corresponding hypotenuse?

$$h = \sqrt{(400)^2 + (600)^2} = 721.11 \text{ yds., Ans.}$$

2. The sides about a right angle are 13 *ft.*, and 25 *ft.*; what is the corresponding hypotenuse? *Ans.* 28.18 *ft.*

3. What is the diagonal of a rectangle whose sides are 14 *rds.*, and 19 *rds.*? *Ans.* 23.6 *rds.*

4. The radius of the base of a cone is $4\frac{1}{2}$ *ft.*, and its altitude is 6 *ft.*; what is its slant height? *Ans.* 7.5 *ft.*

5. The hypotenuse of a right-angled triangle is 45 *yds.*, and one side about the right angle is 37 *yds.*; what is the other side?

$$\text{side} = \sqrt{(45)^2 - (37)^2} = 25.61 \text{ yds., Ans.}$$

6. The radius of the upper base of a conic frustum is 8 *ft.*, the radius of the lower base is 14 *ft.*, and the altitude is 6 *ft.*; what is the slant height?

$$s = \sqrt{(14 - 8)^2 + (6)^2} = 8.49 \text{ ft., Ans.}$$

2°. To find the circumference of a circle whose radius is given.

R U L E .

Multiply twice the radius by 3.1416, (P. 11, B. 5, Cor. 2).

EXAMPLES.

1. The radius of a circle is 3.75 *ft.*, what is its circumference?

$$c = 7.5 \times 3.1416 = 23.56 \text{ ft., Ans.}$$

2. What is the circumference of a circle whose radius is 15.375 *rds.*? *Ans.* 96.60 *rds.*

3. Find the circumference whose radius is 30.25.

$$\text{Ans. } 190.07.$$

3°. To find the length of an arc of a circle whose radius is given.

RULE.

Multiply the length of the circumference, by the number of degrees in the arc, and divide the product by 360, (P. 11, B. 5, Cor. 4).

EXAMPLES.

1. What is the length of an arc of 30°, in a circle whose radius is 20.5 yds.?

$$a = 41 \times 3.1416 \times \frac{30}{360} = \frac{128.81}{12} = 10.73 \text{ yds., Ans.}$$

2. Find the length of an arc of 17°, the radius being equal to 25.5. Ans. 7.57.

3. The radius of a circle is 25.75; what is the length of an arc of 66° 30'? Ans. 29.89.

4. The length of a circumference is 179.86 ft.; what is the length of its radius?

$$r = \frac{179.86}{2\pi} = 28.63 \text{ ft., Ans.}$$

5. The radius of a circle is 31½ ft., and the length of an arc of its circumference, is 16.36 feet; what is the corresponding angle at the centre?

$$n = \frac{16.36}{2\pi r} \times 360^\circ = 30^\circ, \text{ nearly, Ans.}$$

II. MENSURATION OF SURFACES.

Surfaces considered.

7. The surfaces treated of in Elementary Geometry are plane, spherical, conical, and cylindrical.

4°. To find the area of a plane triangle when the base and altitude are given.

R U L E .

Multiply the base by the altitude, and divide the result by 2, (P. 4, B. 4).

EXAMPLES.

1. What is the area of a triangle whose base is 1300 ft., and whose altitude is 520 ft.?

$$A = \frac{1300 \times 520}{2} = 338,000 \text{ sq. ft., Ans.}$$

2. Find the area of a triangle whose base is $13\frac{1}{2}$ yds., and whose altitude is 10 yds.?

Ans. $66\frac{3}{4}$ sq. yds.

3. The base of a triangle is 49 yds., and its altitude is $21\frac{1}{2}$ yds.; what is its area?

Ans. 518 sq. yds.

5°. To find the area of a plane triangle, when two sides and their included angle are given.

8. Let the sides AC, AD, and the angle A, of the triangle ACD, be given. Call AC the base.

From D, draw DE perpendicular to the base; DE will be the altitude. Let the angles of the triangle be denoted by A, C, and D; and let their opposite sides be denoted by a, c, and d.

Then, whether E falls on AC, or on its prolongation, we shall have, (Trig., Art. 29),

$$DE = c \sin A.$$

If we denote the area of the triangle by T , we shall have, from the preceding article,

$$2T = cd \sin A; \dots \dots \dots (1)$$

applying logarithms to formula (1), we have,

$$\log (2T) = \log c + \log d + \log \sin A - 10; \dots (2)$$

hence, we have the following

R U L E .

Find the logarithms of the given sides and the logarithmic sine of their included angle, and take their sum; from this sum subtract 10; the result will be the logarithm of twice the area of the triangle. Find the number corresponding to this logarithm and divide it by 2; the quotient will be the required area.

EXAMPLES.

1. Given, $c = 153$ ft., $d = 211$ ft., and $A = 62^\circ 20'$, to find the area of the triangle.

OPERATION.

$\log 153$	2.184691
$\log 211$	2.324282
$\log \sin 62^\circ 20'$	9.947269

$$\therefore 2T = \log^{-1} 4.456242 = 28,591.84;$$

hence, $T = 14,295.92$ sq. ft., *Ans.*

2. What is the area of a triangle, two of whose sides are 60 yds. and 80 yds., their included angle being $28^\circ 57'$?

Ans. 1161.71 sq. yds.

3. Two sides of a triangular field are respectively 25 rds., and $21\frac{1}{4}$ rds. in length, and their included angle is 45° ; what is the area of the field?

Ans. 187.82 sq. rds. = 1 A. 27.82 sq. rds.

6°. To find the area of a plane triangle when its three sides are given.

LEMMA.

To find expressions for the sine and for the cosine of half an angle of a plane triangle.

9. Assume the figure and the notation of the last article; and let it be required to find the sine and the cosine of $\frac{1}{2}C$.

From P. 9, and P. 10, B. 4, we have,

$$\overline{DA}^2 = \overline{AC}^2 + \overline{CD}^2 \mp 2\overline{AC} \times \overline{CE}$$

$$\text{or, } c^2 = d^2 + a^2 \mp 2d \times \overline{CE} . (1)$$

The upper sign corresponds to the case in which C is acute, and the lower sign to the case in which C is obtuse.

Now, when C is acute, we have,

$$CE = CD \cos C, \text{ or, } CE = a \cos C;$$

when C is obtuse, we have,

$$CE = CD \cos DCE = - CD \cos C, \text{ or, } CE = - a \cos C.$$

If we substitute the first value of CE in (1), taking the upper sign of the last term; or if we substitute the second value taking the lower sign, we shall have, in both cases,

$$c^2 = d^2 + a^2 - 2ad \cos C;$$

whence,

$$\cos C = \frac{d^2 + a^2 - c^2}{2ad} (2)$$

If we add 1 to both members of equation (2), remembering that $1 + \cos C = 2 \cos^2 \frac{1}{2}C$, (*Trig., Art. 43*), we shall have, after reduction,

$$\cos^2 \frac{1}{2}C = \frac{d^2 + a^2 + 2ad - c^2}{4ad} = \frac{(a+d)^2 - c^2}{4ad} \quad (3)$$

The numerator of the final member of (3) can be factored, giving,

$$(a+d)^2 - c^2 = (a+d+c)(a+d-c);$$

hence, equation (3) may be written,

$$\cos^2 \frac{1}{2}C = \frac{\frac{1}{2}(a+c+d) \frac{1}{2}(a+d-c)}{ad} \quad (4)$$

If we denote the sum of the sides by s , we shall have,

$$\frac{1}{2}(a+c+d) = \frac{1}{2}s, \text{ and } \frac{1}{2}(a+d-c) = \frac{1}{2}s - c.$$

which substituted in (4) give,

$$\cos^2 \frac{1}{2}C = \frac{\frac{1}{2}s (\frac{1}{2}s - c)}{ad}, \text{ or, } \cos \frac{1}{2}C = \sqrt{\frac{\frac{1}{2}s (\frac{1}{2}s - c)}{ad}} \quad (5)$$

If we now subtract both members of equation (2) from 1, remembering that $1 - \cos C = 2 \sin^2 \frac{1}{2}C$, (*Trig., Art. 43*), we shall have, after reduction,

$$\sin^2 \frac{1}{2}C = \frac{c^2 + 2ad - d^2 - a^2}{4ad} = \frac{c^2 - (a-d)^2}{4ad} \quad (6)$$

Factoring the final member of (6), we have,

$$\sin^2 \frac{1}{2}C = \frac{\frac{1}{2}(c+a-d) \frac{1}{2}(c+d-a)}{ad} \quad (7)$$

But we have,

$$\frac{1}{2}(c+a-d) = \frac{1}{2}s - d, \text{ and } \frac{1}{2}(c+d-a) = \frac{1}{2}s - a.$$

Substituting these in (7), we have,

$$\sin^2 \frac{1}{2}C = \frac{(\frac{1}{2}s-d)(\frac{1}{2}s-a)}{ad}, \text{ or } \sin \frac{1}{2}C = \sqrt{\frac{(\frac{1}{2}s-d)(\frac{1}{2}s-a)}{ad}}. \quad (8)$$

Equations (5) and (8) give the required functions of $\frac{1}{2}C$.

To find the area of ACD.

10. Let the area of ACD be denoted by T. We have from formula (1), *Art.* 8,

$$2T = ad \sin C. \quad (9)$$

But, $\sin C = 2 \sin \frac{1}{2}C \cos \frac{1}{2}C$, (*Trig.*, *Art.* 42);

whence, by substitution and reduction,

$$T = ad \sin \frac{1}{2}C \cos \frac{1}{2}C. \quad (11)$$

Substituting the values of $\sin \frac{1}{2}C$, and $\cos \frac{1}{2}C$, taken from (8) and (5), we have

$$T = \sqrt{\frac{1}{2}s(\frac{1}{2}s-a)(\frac{1}{2}s-b)(\frac{1}{2}s-c)}. \quad (12)$$

Hence, we may find the area of a plane triangle by the following

RULE.

Find half the sum of the three sides, and from it subtract each side separately; then find the continued product of the half sum and the three remainders; extract the square root of the product.

If we apply logarithms to formula (12), we have,

$$\log T = \frac{1}{2}[\log \frac{1}{2}s + \log (\frac{1}{2}s - a) + \log (\frac{1}{2}s - b) + \log (\frac{1}{2}s - c)].$$

EXAMPLES.

1. Given, $a = 75$ ft., $b = 115$ ft., and $c = 140$ ft., to find the area of the triangle.

OPERATION.

$\frac{1}{2}s = 165$, $\frac{1}{2}s - a = 90$, $\frac{1}{2}s - b = 50$, and $\frac{1}{2}s - c = 25$.

log 165 . . . 2.217484

log 90 . . . 1.954243

log 50 . . . 1.698970

log 25 . . . 1.397940

2) 7.268637

$T = \log^{-1} 3.634318 = 4,308.42 \text{ sq. ft.}$, *Ans.*

2. Given, $a = 90 \text{ ft.}$, $b = 120 \text{ ft.}$, and $c = 150 \text{ ft.}$, to find the area of the triangle. *Ans. 5400 sq. ft.*

3. The sides of a triangular field are 196 *rds.*, 201 *rds.*, and 102.76 *rds.*; how many acres in the field?

Ans. 61 A. 79.68 sq. rds.

4. Find the area of an equilateral triangle, each of whose sides is equal to 75 *ft.* *Ans. 2435.7 sq. ft.*

7°. To find the area of a parallelogram whose base and altitude are given.

RULE.

Multiply the base by the altitude, (P. 2, B. 4).

EXAMPLES.

1. What is the area of a parallelogram whose base is 25.5 *ft.*, and whose altitude is 17 *ft.*? *Ans. 433.5 sq. ft.*

2. The base of a parallelogram is equal to 34.8 *rds.*, and its altitude is 24 *rds.*; how many acres in the field?

Ans. 5.22 A.

3. How many square yards of carpeting will be required to carpet a room 42 *ft.* long and 19 *ft.* wide?

Ans. 88 $\frac{1}{2}$ yds.

If two adjacent sides and their included angle are given, we have the following

R U L E .

Find the continued product of the two sides and the sine of their included angle.

4. The adjacent sides of a parallelogram are 20 yds., and 37 yds., and their included angle is 43° ; what is the area of the parallelogram?

$$\log (\text{area}) = \log 20 + \log 37 + \log \sin 43^\circ - 10;$$

$$\therefore \text{area} = 504.7 \text{ sq. yds., Ans.}$$

5. The adjacent sides of a parallelogram are 125.81, and 57.65; and their included angle is $57^\circ 25'$; what is the area of the parallelogram? *Ans.* 6111.4.

8°. *To find the area of a trapezoid.*

R U L E .

Multiply the half sum of its parallel bases by the altitude, (P. 5, B. 4).

EXAMPLES.

1. The parallel sides of a trapezoid are 20.25 ft., and 12.75 ft., and the altitude is 9.75 ft.; what is the area of the trapezoid?

$$\frac{1}{2}(20.25 + 12.75) \times 9.75 = 160.88 \text{ sq. ft., Ans.}$$

2. The parallel sides of a trapezoidal field measure 30 rds., and 49 rds., and the perpendicular distance between them is 61.6 rds.; how many acres does the field contain?

$$\text{Ans. } 15\frac{1}{4} \text{ A., nearly.}$$

3. The length of a board is 14.5 ft.; its breadth at the

wider end is 16 in., and at the narrower end 11.6 in.; what is its superficial content? *Ans.* $16\frac{2}{3}$ sq. ft.

9°. To find the area of a regular polygon.

11. Let ACDEF be a regular polygon, whose centre is O; let OP be its apothem, OA, OC, OD, OE, and OF, radii, dividing it into equal isosceles triangles. Then, its area is equal to the length of one side multiplied by the number of sides, into one-half of the apothem, (P. 4, B. 5).

If we denote the area by A , the length of one side by s , the apothem by a , and the number of sides by n , we shall have

$$A = s \times n \times \frac{1}{2}a, \text{ or } A = \frac{1}{2}сна. \quad (1)$$

The angle AOP is equal to $\frac{360^\circ}{2n}$, or to $\frac{180^\circ}{n}$, (Art. 87, *Geom.*). From the right-angled triangle APO, we have,

$$PA = OP \tan AOP, \text{ or, } \frac{1}{2}s = a \tan \frac{180^\circ}{n};$$

$$\therefore a = \frac{1}{2}s \cot \frac{180^\circ}{n}. \quad (2)$$

Substituting in (1), and reducing, we have,

$$A = \frac{1}{4}ns^2 \cot \frac{180^\circ}{n}. \quad (3)$$

Hence, the following

R U L E .

Multiply one-fourth the square of one side by the cotangent of half the angle at the centre into the number of sides.

EXAMPLES.

1. Find the area of a regular hexagon, one of whose sides is 20 *yds.*

Applying logarithms to formula (3), we have,

$$\log 4A = \log n + 2 \log s + \log \cot \frac{180^\circ}{n} - 10.$$

Substituting for n and s their values as given above, we have,

$$\log 4A = \log 6 + 2 \log 20 + \log \cot 30^\circ - 10 = 3.618772.$$

$$\therefore 4A = 4156.91 \text{ sq. yds., or, } A = 1039.23 \text{ sq. yds., Ans.}$$

2. The side of a regular octagon is 25 *ft.*; what is its area? *Ans.* 3017.77 *sq. ft.*

3. The side of a regular pentagon is 22 *yds.*; what is its area? *Ans.* 832.71 *sq. yds.*

4. The side of a regular decagon is 15 *ft.*; what is its area? *Ans.* 1731.2 *sq. ft.*

Note.—To find the area of any polygon, we divide it into triangles, by diagonals drawn from any vertex; we then determine the length of each diagonal; we next compute the area of each triangle by the method explained in *Art.* 10; the sum of the areas of these triangles will be the required area.

10°. To find the area of a circle whose radius is given.

RULE.

Multiply the square of the radius by 3.1416, (*P.* 11, *Cor.* 3, *B.* 5).

EXAMPLES.

1. What is the area of a circle whose radius is 30 *in.*?

$$A = (30)^2 \times 3.1416 = 2827.44 \text{ sq. in., Ans.}$$

2. Find the area of a circle whose radius is 4.75 *rds.*

Ans. 70.88 *sq. rds.*

3. The radius of a circle is 8.25 *yds.*; what is its area?

Ans. 213.83 *sq. yds.*

4. What is the area of a circular pond, whose diameter is 12.75 *rds.*?

Ans. 127.68 *sq. rds.*

5. The diameter of a circular park is 77.75 *rds.*; how many acres does it contain?

Ans. 29.67 *A.*

To find the area of a circular sector, we first find the area of the circle to which it belongs; we then multiply this area by the quotient obtained, by dividing the angle of the sector by 360° .

6. What is the area of a sector of 60° , in a circle whose radius is 42 *yds.*?

Circle = 5541.78 *sq. yds.*, \therefore sector = $\frac{1}{6} \times 5541.78$, or 923.63 *sq. yds.*, *Ans.*

7. The angle of a sector is 45° , and its radius 4.75 *ft.*; what is its area?

Ans. 8.86 *sq. ft.*

To find the area of a circular segment ACD, we first find the area of the sector AODC; we then subtract from it the area of the triangle AOD; the difference is the required area.

8. What is the area of a circular segment corresponding to an angle of 120° at the centre, the radius of the circle being 20 *ft.*?

Ans. 245.68 *sq. ft.*

11°. To find the area of the lateral surface of a right prism, or of a cylinder.

RULE.

Multiply the perimeter of either base, by the altitude, (P. 3, B. 7, and P 1, Cor. 2, B. 8).

EXAMPLES.

1. The perimeter of the base of a right prism is 20 *ft.* and its altitude is 10 *ft.*; what is the area of its lateral surface?

Ans. 200 *sq. ft.*

2. The base of a right prism is a regular pentagon, one of whose sides is 25 *in.* and the altitude of the prism is 12 *ft.*; what is the entire surface of the prism, including the bases?

Ans. 139.93 *sq. ft.*

3. The radius of the base of a right cylinder is 10 *in.*, and the altitude of the cylinder is 6 *in.*; what is its entire surface?

Ans. 1005.31 *sq. in.*

12°. To find the area of the lateral surface of a right pyramid, or of a cone.

RULE.

Multiply the perimeter of the base by one-half the slant height, (P. 4, B. 7, and P. 2, Cor. 4, B. 8.)

EXAMPLES.

1. The perimeter of the base of a right pyramid is 40 *ft.*, and the slant height is 4 *ft.*; what is the area of its lateral surface?

Ans. 80 *sq. ft.*

2. The radius of the base of a right cone is 3 *ft.*, and the altitude of the cone is 4 *ft.*; what is its lateral surface?

Ans. 47.12 *sq. ft.*

3. The radius of the base of a cone is 2 *ft.*, and the altitude of the cone is 6 *ft.*; what is the area of its entire surface, including the base?

Ans. 52.31 *sq. ft.*

To find the lateral surface of a frustum of a right pyramid, or of a cone, we multiply the half sum of the perimeters of the upper and lower bases, by the slant height, (P. 4, Cor., B. 7, and P. 3, Cor. 2, B. 8.)

4. The perimeter of the upper base of a frustum of a right

pyramid is 18 *ft.*, the perimeter of its lower base is 28 *ft.*, and its slant height is 6 *ft.*; what is the area of its lateral surface? *Ans.* 138 *sq. ft.*

5. The radius of the upper base of a conic frustum is 3 *ft.*, the radius of the lower base is 4 *ft.*, and the slant height is 8 *ft.*; what is its entire surface, including both bases? *Ans.* 254.46 *sq. ft.*

13°. *To find the area of the surface of a sphere.*

RULE.

Multiply 4 times the square of the radius by 3.1416, (P. 7, Cor. 1, B. 8.)

EXAMPLES.

1. What is the area of the surface of a sphere whose radius is 20 *in.*?

$$4 \times 20^2 \times 3.1416 = 5026.56 \text{ sq. in., } \textit{Ans.}$$

2. What is the area of the surface of a sphere whose diameter is 5 *ft.*? *Ans.* 78.54 *sq. ft.*

To find the area of a zone, we multiply twice the radius, by the altitude of the zone, and that result by π , (P. 7, Cor. 3, B. 8.)

3. Find the area of a zone, on a sphere, whose radius is 7 *ft.*, the altitude of the zone being 3 *ft.* *Ans.* 131.95 *sq. ft.*

4. The radius of the earth, considered as a sphere, is equal to 3,956 miles, the latitude of the tropic of cancer is $23^\circ 30'$, and that of the arctic circle is $66^\circ 30'$; what is the area of the northern temperate zone? *Ans.* 50,966,183.59 *sq. mi.*

The altitude is equal to $3956 (\sin 66^\circ 30' - \sin 23^\circ 30')$; the natural sines of $66^\circ 30'$ and $23^\circ 30'$ are .91706 and .39875, hence the altitude is 2050.43 miles.

14°. *To find the area of a spherical triangle.*

•
R U L E.

Diminish the sum of its angles by 180° , and divide the result by 90° ; this will give the spherical excess. Multiply one-half the square of the radius by 3.1416; this will give the area of the tri-rectangular rectangle. Then, multiply the area of the tri-rectangular triangle by the spherical excess, (P. 16, B. 9).

E X A M P L E S.

1. The angles of a spherical triangle are 85° , 105° , and 50° ; the radius of the sphere on which the triangle is situated is 22.25 ft.; what is the area of the triangle?

Ans. 518.43 sq. ft.

The spherical excess is $\frac{1}{2}$; the area of the tri-rectangular triangle is 777.64 sq. ft.

2. The angles of a spherical triangle are 140° , 92° , and 68° ; the radius of the sphere is 30 ft.; what is the area of the triangle?

Ans. 1884.96 sq. ft.

III. MENSURATION OF VOLUMES.

Volumes considered.

12. The volumes treated of in elementary Geometry are the prism, and the cylinder; the pyramid, the cone, and their frustums; and the sphere.

15°. *To find the volume of a prism, or of a cylinder.*

R U L E.

Multiply the area of its base by its altitude, (P. 14, B. 7, and P. 1, Cor. 3, B. 8.)

E X A M P L E S.

1. Find the volume of a block of stone whose length is $3\frac{1}{2}$ ft., whose breadth is $2\frac{2}{3}$ ft., and whose altitude is $2\frac{1}{2}$ ft.

Base = $3\frac{1}{2} \times 2\frac{2}{3} = 8\frac{4}{3}$ sq. ft.; $\therefore 8\frac{4}{3} \times 2\frac{1}{2} = 21\frac{1}{3}$ cu. ft., *Ans.*

2. The sides of the base of a triangular prism are 3 yds., 4 yds., and 5 yds.; and the altitude of the prism is 6 yds.; what is the volume of the prism? *Ans.* 36 cu. yds.

3. What is the volume of a cylinder, the radius of whose base is 4.5 yds., and whose altitude is 11 yds.?

Ans. 699.79 cu. yds.

4. The radius of the base of cylindrical log is 9 in., and its length is 21 ft.; what are its cubic contents?

Ans. 37.1 cu. ft.

5. What is the content of a cylindrical vat 15 ft. in diameter, and 12 ft. deep?

Ans. 2120.58 cu. ft.

16°. To find the volume of a right pyramid, or of a cone.

RULE.

Multiply the area of its base by one-third of its altitude, (P. 17, B. 7, and P. 2, Cor. 5, B. 8).

EXAMPLES.

1. The area of the base of a pyramid is 74.3 sq. yds., and its altitude is 21 yds.; what is its volume?

Ans. 520.1 cu. yds.

2. The base of a right pyramid is a regular pentagon, each side of which is equal to 10 ft.; and its altitude is 18 ft.; what is its volume?

Ans. 1032.29 cu. ft.

3. The radius of the base of a right cone is 8.5 yds., and its altitude is 15.75 yds.; what is its content?

Ans. 1191.65 cu. yds.

4. The radius of the base of a cone is 3 ft., and its slant height is 5 ft.; what is its volume?

Ans. 37.7 cu. ft.

17°. To find the volume of a frustum of a right pyramid, or of a frustum of a cone.

RULE.

Find the sum of the upper base, the lower base, and a mean proportional between the two bases; then multiply this sum by one-third of the altitude, (P. 18, Cor. 2, B. 7, and P. 3, Cor. 3, B. 8.)

EXAMPLES.

1. The upper base of a pyramidal frustum is 7.2 sq. yds., the lower base is 12.5 sq. yds., and the altitude of the frustum is 6 yds.; what is its cubic content?

Ans. $(7.2 + 12.5 + \sqrt{7.2 \times 12.5}) \times 2 = 58.37$ cu. yds.

2. The bases of a pyramidal frustum are regular hexagons; one side of the upper base is 2 ft., one side of the lower base is 3 ft., and the altitude of the frustum is 7 ft.; what is the volume of the frustum?

Ans. 115.178 cu. ft.

3. The radius of the upper base of a conic frustum is 3.5 ft., the radius of its lower base is 14 ft., and the altitude of the frustum is 33 ft.; what is its volume?

Ans. 8,889.92 cu. ft.

4. The radius of the upper base of a conic frustum is 2.5 ft., the radius of its lower base is 3.5 ft., and its altitude is 6 ft.; what is the volume of the frustum?

Ans. 171.22 cu. ft.

18°. *To find the volume of a sphere,*

RULE

Multiply four-thirds of the cube of the radius by 3.1416, (P. 8, Cor. 1, B. 8.)

The factor $\frac{4}{3}\pi$ is equal to 4.1888; $\therefore V = 4.1888R^3$.

EXAMPLES.

1. Find the volume of a sphere whose radius is 3 *ft.*

$$V = 41888 \times 27 = 113.1 \text{ cu. ft., nearly, Ans.}$$

2. What is the volume of a sphere whose radius is 2 *yds.*?

Ans. 33.51 *cu. yds.*

To find the volume of a spherical sector, we first find the area of the zone which forms its base; we then multiply this by one-third the radius.

3. The altitude of a zone, on a sphere whose radius is 10 *ft.*, is 3 *ft.*; what is the volume of the corresponding spherical sector?

Ans. 628.32 *cu. ft.*

The area of the zone is found by Rule 13°.

4. The area of a zone, on the surface of a sphere whose radius is 11 *yds.*, is equal to 276 *sq. yds.*; what is the volume of the corresponding spherical sector?

Ans. 1012 *cu. yds.*

5. What is the radius of a sphere whose volume is 417 *cu. yds.*?

Ans. 4.63 *yds.*

19°. To find the volume of a wedge.

Definitions.

3. A **wedge** is a polyedron, bounded by a parallelogram, two trapezoids, and two triangles; as, ACDE-PQ.

The parallelogram AD, is called the **back**; the trapezoids AQ and EQ, are called **faces**; the triangles APE and CQD, are called **ends**;

the line PQ, in which the faces meet and which is parallel

to the back, is called the **edge**; and a line OT , drawn from any point of the edge, perpendicular to the back, is called the **altitude** of the wedge.

14. If a plane is passed through V , the middle of the altitude, and parallel to the back of the wedge, its intersection with the wedge is called the **middle section** of the wedge; thus, $FGSL$ is the middle section of the wedge $ACDE$ - PQ .

15. A **frustum** of a wedge is the part included between the back and any secant plane parallel to the back; thus, $ACDE$ - $FGSL$ is a frustum of the wedge $ACDE$ - PQ .

Expression for the volume.

16. Let us first suppose that the length of the edge is less than the length of the back. Through the extremity Q , of the edge PQ , pass a plane QNM parallel to PAE ; this plane will divide the wedge into a triangular prism QNM - A , and a pyramid, $NCDM$ - Q . Through the middle of the altitude, pass a plane parallel to $ACDE$; it will intersect the prism and the pyramid in the *middle sections* FH and KS .

Denote the area of $ANME$ by b , of $NCDM$ by b' , of $FKHL$ by m , and of $KGSH$ by m' ; also denote the altitude by $6h$.

The triangular prism $ANME$ - P , is the half of a parallelepipedon whose edges are ME , MN , and MQ ; hence, the volume of this prism is equal to $ANME \times \frac{1}{2}OT$, that is, to $b \times 3h$. The altitude of the pyramid is equal to OT ; hence, its volume is equal to $NCDM \times \frac{1}{3}OT$, that is, to $b' \times 2h$. Denoting the volume of the wedge by V , and the area of its back by B , we have,

$$V = h [3b + 2b'] = h [(b + b') + 2b + b'] = h [B + 2b + b']. \quad (1)$$

Now, KF is equal to AN, and KH to $\frac{1}{2}$ NM; hence, ANME is equal twice FKHL, that is, b is equal to $2m$; also, GK is equal to $\frac{1}{2}$ CN, and HK to $\frac{1}{2}$ NM; hence, NCDM is equal to 4 times KGSH, that is, b' is equal to $4m'$; hence,

$$2b + b' = 4m + 4m' = 4(m + m');$$

denoting the sum of m and m' , that is, the middle section of the wedge, by M , and substituting in (1), we have,

$$V = h [B + 4M]. \quad \dots \dots \dots (2)$$

If the length of the edge is greater than the length of the back, the volume of the wedge is equal to the difference of the volumes of the prism and the pyramid, and the expression for the volume is of the same form as before.

We may therefore find the volume of a wedge by the following

R U L E .

To the area of the back add four times the middle section, and multiply the sum by one-sixth of the altitude.

EXAMPLES.

1. The length of the back of a wedge is 30 *ft.*, the breadth of the back is 20 *ft.*, the length of the edge is 40 *ft.*, and the altitude is 18 *ft.*; what is its volume? *Ans.* 6000 *cu. ft.*

The length of the middle section is $\frac{1}{2}(30 \text{ ft} + 40 \text{ ft.})$, or 35 *ft.*, and the breadth of that section $\frac{1}{2}(20) \text{ ft.}$, or 10 *ft.*

2. The back of a wedge is 18 *ft.* long, and 9 *ft.* wide; the edge is 20 *ft.* long; and the altitude is 6 *ft.*: what is its volume? *Ans.* 504 *cu. ft.*

20°. *To find the volume of a prismoid.*

Definitions.

17. A **prismoid** is a frustum of a wedge, (*Art.* 15); thus, ACDE-PQRT is a prismoid.

The parallel faces, ACDE and PQRT, are called **bases**; the perpendicular distance between the bases is called the **altitude** of the prismoid; and the section FGHK, through the middle of the altitude and parallel to the bases, is the **middle section** of the prismoid.

Expression for the Volume.

18. Let the volume of the prismoid be denoted by V , its lower base by B , its upper base by B' , its middle section by M , and its altitude by $6h$.

Pass a plane through PQ and DE ; this will divide the prismoid into two wedges, having the same altitude as the prismoid. The back of the first wedge is equal to B , and its middle section is $FGSL$; the back of the second wedge is B' and its middle section is $LSHK$.

Because the prismoid is equal to the sum of the two wedges, we have, (*Art.* 16),

$$\dot{V} = h[B + 4FGSL] + h[B' + 4LSHK] = h[B + B' + 4M]. \quad (1)$$

We may therefore find the volume of a prismoid by the following

RULE.

Find the sum of the end sections together with four times the middle section, and multiply the result by one-sixth of the altitude.

EXAMPLES.

1. The length of the lower base of a prismoid is 24 *ft.*, its breadth 18 *ft.*; the length of the upper base is 16 *ft.*, and its breadth 14 *ft.*; and the altitude of the prismoid is 27 *ft.*: what is its volume ?

Ans. 8,712 *cu. ft.*

The length of the middle section is $\frac{1}{2}(24 \text{ ft.} + 16 \text{ ft.})$, or 20 *ft.*, and the breadth of that section is $\frac{1}{2}(18 \text{ ft.} + 14 \text{ ft.}) = 16 \text{ ft.}$

2. The end sections of a volume of earth are respectively 340 *sq. ft.*, and 590 *sq. ft.*; the middle section is 475 *sq. ft.*; and the length of the section is 100 *ft.*: what is the volume of earth ?

Ans. 47,166 $\frac{2}{3}$ *cu. ft.*

3. What is the volume of a stick of hewn timber, whose ends are 30 *in.* by 27 *in.*, and 24 *in.* by 18 *in.*, its length being 24 *ft.* ?

Ans. 102 *cu. ft.*

Formula (1), *Art.* 18, is called the *prismoidal formula*; it is used by engineers in computing the volumes of earth-work in railroad cuttings and embankments.

It may be shown that the prismoidal formula holds good for the cone, the cylinder, the pyramid, the frustum of a cone, the frustum of a pyramid, and for the sphere.

In the cone, one of the end sections is 0; in the sphere, both of the end sections are 0 and the middle section is a great circle.

Let the student show that the formula gives the correct volume in each of the cases just named.

A TABLE
OF
LOGARITHMIC
SINES AND TANGENTS
FOR EVERY
DEGREE AND MINUTE
OF THE QUADRANT.

REMARK. The minutes in the left-hand column of each page, increasing downwards, belong to the degrees at the top; and those increasing upwards, in the right-hand column, belong to the degrees below.

M.	Sine	D.	Cosine	D.	Tang.	D.	Cotang.

MATHEMATICS.

DAVIES'S COMPLETE SERIES.

ARITHMETIC.

- Davies' Primary Arithmetic.
- Davies' Intellectual Arithmetic.
- Davies' Elements of Written Arithmetic.
- Davies' Practical Arithmetic.
- Davies' University Arithmetic.

TWO-BOOK SERIES.

- First Book in Arithmetic, Primary and Mental.
- Complete Arithmetic.

ALGEBRA.

- Davies' New Elementary Algebra.
- Davies' University Algebra.
- Davies' New Bourdon's Algebra.

GEOMETRY.

- Davies' Elementary Geometry and Trigonometry.
- Davies' Legendre's Geometry.
- Davies' Analytical Geometry and Calculus.
- Davies' Descriptive Geometry.
- Davies' New Calculus.

MENSURATION.

- Davies' Practical Mathematics and Mensuration.
- Davies' Elements of Surveying.
- Davies' Shades, Shadows, and Perspective.

MATHEMATICAL SCIENCE.

- Davies' Grammar of Arithmetic.
- Davies' Outlines of Mathematical Science.
- Davies' Nature and Utility of Mathematics.
- Davies' Metric System.
- Davies & Peck's Dictionary of Mathematics.

DAVIES'S NATIONAL COURSE OF MATHEMATICS.

ITS RECORD.

In claiming for this series the first place among American text-books, of whatever class, the publishers appeal to the magnificent record which its volumes have earned during the *thirty-five years* of Dr. Charles Davies's mathematical labors. The unremitting exertions of a life-time have placed *the modern series* on the same proud eminence among competitors that each of its predecessors had successively enjoyed in a course of constantly improved editions, now rounded to their perfect fruition, — for it seems almost that this science is susceptible of no further demonstration.

During the period alluded to, many authors and editors in this department have started into public notice, and, by borrowing ideas and processes original with Dr. Davies, have enjoyed a brief popularity, but are now almost unknown. Many of the series of to-day, built upon a similar basis, and described as "modern books," are destined to a similar fate; while the most far-seeing eye will find it difficult to fix the time, on the basis of any data afforded by their past history, when these books will cease to increase and prosper, and fix a still firmer hold on the affection of every educated American.

One cause of this unparalleled popularity is found in the fact that the enterprise of the author did not cease with the original completion of his books. Always a practical teacher, he has incorporated in his text-books from time to time the advantages of every improvement in methods of teaching, and every advance in science. During all the years in which he has been laboring he constantly submitted his own theories and those of others to the practical test of the class-room, approving, rejecting, or modifying them as the experience thus obtained might suggest. In this way he has been able to produce an almost perfect series of class-books, in which every department of mathematics has received minute and exhaustive attention.

Upon the death of Dr. Davies, which took place in 1876, his work was immediately taken up by his former pupil and mathematical associate of many years, Prof. W. G. Peck, LL.D., of Columbia College. By him, with Prof. J. H. Van Amringe, of Columbia College, the original series is kept carefully revised and up to the times.

DAVIES'S SYSTEM IS THE ACKNOWLEDGED NATIONAL STANDARD FOR THE UNITED STATES, for the following reasons:—

1st. It is the basis of instruction in the great national schools at West Point and Annapolis.

2d. It has received the *quasi* indorsement of the National Congress.

3d. It is exclusively used in the public schools of the National Capital.

4th. The officials of the Government use it as authority in all cases involving mathematical questions.

5th. Our great soldiers and sailors commanding the national armies and navies were educated in this system. So have been a majority of eminent scientists in this country. All these refer to "Davies" as authority.

6th. A larger number of American citizens have received their education from this than from any other series.

7th. The series has a larger circulation throughout the whole country than any other, being *extensively used in every State in the Union*.

DAVIES AND PECK'S ARITHMETICS.

OPTIONAL OR CONSECUTIVE.

The best thoughts of these two illustrious mathematicians are combined in the following beautiful works, which are the natural successors of Davies's *Arithmetics*, sumptuously printed, and bound in crimson, green, and gold:—

Davies and Peck's Brief Arithmetic.

Also called the "Elementary Arithmetic." It is the shortest presentation of the subject, and is *adequate* for all grades in common schools, being a thorough introduction to practical life, except for the specialist.

At first the authors play with the little learner for a few lessons, by object-teaching and kindred allurements; but he soon begins to realize that study is earnest, as he becomes familiar with the simpler operations, and is delighted to find himself master of important results.

The second part reviews the Fundamental Operations on a scale proportioned to the enlarged intelligence of the learner. It establishes the General Principles and Properties of Numbers, and then proceeds to Fractions. Currency and the Metric System are fully treated in connection with Decimals. Compound Numbers and Reduction follow, and finally Percentage with all its varied applications.

An Index of words and principles concludes the book, for which every scholar and most teachers will be grateful. How much time has been spent in searching for a half-forgotten definition or principle in a former lesson!

Davies and Peck's Complete Arithmetic.

This work certainly deserves its name in the best sense. Though complete, it is not, like most others which bear the same title, *cumbersome*. These authors excel in clear, lucid demonstrations, teaching the science pure and simple, yet not ignoring convenient methods and practical applications.

For turning out a thorough business man no other work is so well adapted. He will have a clear comprehension of the science as a whole, and a working acquaintance with details which must serve him well in all emergencies. Distinguishing features of the book are the logical progression of the subjects and the great variety of practical problems, not *puzzles*, which are beneath the dignity of educational science. A clear-minded critic has said of Dr. Peck's work that it is free from that juggling with numbers which some authors falsely call "Analysis." A series of Tables for converting ordinary weights and measures into the Metric System appear in the later editions.

PECK'S ARITHMETICS.

Peck's First Lessons in Numbers.

This book begins with pictorial illustrations, and unfolds gradually the science of numbers. It noticeably simplifies the subject by developing the principles of addition and subtraction simultaneously; as it does, also, those of multiplication and division.

Peck's Manual of Arithmetic.

This book is designed especially for those who seek sufficient instruction to carry them successfully through practical life, but have not time for extended study.

Peck's Complete Arithmetic.

This completes the series but is a much briefer book than most of the complete arithmetics, and is recommended not only for what it contains, but also for what is omitted.

It may be said of Dr. Peck's books more truly than of any other series published, that they are clear and simple in definition and rule, and that superfluous matter of every kind has been faithfully eliminated, thus magnifying the working value of the book and saving unnecessary expense of time and labor.

THE NATIONAL SERIES OF STANDARD SCHOOL-BOOKS.

Algebra. The student's progress in Algebra depends very largely upon the proper treatment of the four *Fundamental Operations*. The terms *Addition*, *Subtraction*, *Multiplication*, and *Division* in Algebra have a wider meaning than in Arithmetic, and these operations have been so defined as to include their arithmetical meaning; so that the beginner is simply called upon to *enlarge* his views of those fundamental operations. Much attention has been given to the explanation of the negative sign, in order to remove the well-known difficulties in the use and interpretation of that sign. Special attention is here called to "A Short Method of Removing Symbols of Aggregation," Art. 76. On account of their importance, the subjects of *Factoring*, *Greatest Common Divisor*, and *Least Common Multiple* have been treated at greater length than is usual in elementary works. In the treatment of *Fractions*, a method is used which is quite simple, and, at the same time, more general than that usually employed. In connection with *Radical Quantities* the roots are expressed by fractional exponents, for the principles and rules applicable to integral exponents may then be used without modification. The *Equation* is made the chief subject of thought in this work. It is defined near the beginning, and used extensively in every chapter. In addition to this, four chapters are devoted exclusively to the subject of *Equations*. All *Proportions* are equations, and in their treatment as such all the difficulty commonly connected with the subject of Proportion disappears. The chapter on *Logarithms* will doubtless be acceptable to many teachers who do not require the student to master Higher Algebra before entering upon the study of Trigonometry.

HIGHER MATHEMATICS.

Peck's Manual of Algebra.

Bringing the methods of Bourdon within the range of the Academic Course.

Peck's Manual of Geometry.

By a method purely practical, and unembarrassed by the details which rather confuse than simplify science.

Peck's Practical Calculus.

Peck's Analytical Geometry.

Peck's Elementary Mechanics.

Peck's Mechanics, with Calculus.

The briefest treatises on these subjects now published. Adopted by the great Universities: Yale, Harvard, Columbia, Princeton, Cornell, &c.

Macnie's Algebraical Equations.

Serving as a complement to the more advanced treatises on Algebra, giving special attention to the analysis and solution of equations with numerical coefficients.

Church's Elements of Calculus.

Church's Analytical Geometry.

Church's Descriptive Geometry. With plates. 2 vols.

These volumes constitute the "West Point Course" in their several departments. Prof. Church was long the eminent professor of mathematics at West Point Military Academy, and his works are standard in all the leading colleges.

Courtenay's Elements of Calculus.

A standard work of the very highest grade, presenting the most elaborate attainable survey of the subject.

Hackley's Trigonometry.

With applications to Navigation and Surveying, Nautical and Practical Geometry, and Geodesy.

GENERAL HISTORY.

Monteith's Youth's History of the United States.

A History of the United States for beginners. It is arranged upon the catechetical plan, with illustrative maps and engravings, review questions, dates in parentheses (that their study may be optional with the younger class of learners), and interesting biographical sketches of all persons who have been prominently identified with the history of our country.

Willard's United States. School and University Editions.

The plan of this standard work is chronologically exhibited in front of the titlepage. The maps and sketches are found useful assistants to the memory; and dates, usually so difficult to remember, are so systematically arranged as in a great degree to obviate the difficulty. Candor, impartiality, and accuracy are the distinguishing features of the narrative portion.

Willard's Universal History. New Edition.

The most valuable features of the "United States" are reproduced in this. The peculiarities of the work are its great conciseness and the prominence given to the chronological order of events. The margin marks each successive era with great distinctness, so that the pupil retains not only the event but its time, and thus fixes the order of history firmly and usefully in his mind. Mrs. Willard's books are constantly revised, and at all times written up to embrace important historical events of recent date. Professor Arthur Gilman has edited the last twenty-five years to 1882.

Lancaster's English History.

By the Master of the Stoughton Grammar School, Boston. The most practical of the "brief books." Though short, it is not a bare and uninteresting outline, but contains enough of explanation and detail to make intelligible the *cause and effect* of events. Their relations to the history and development of the American people is made specially prominent.

Willis's Historical Reader.

Being Collier's Great Events of History adapted to American schools. This rare epitome of general history, remarkable for its charming style and judicious selection of events on which the destinies of nations have turned, has been skillfully manipulated by Professor Willis, with as few changes as would bring the United States into its proper position in the historical perspective. As reader or text-book it has few equals and no superior.

Berard's History of England.

By an authoress well known for the success of her History of the United States. The social life of the English people is felicitously interwoven, as in fact, with the civil and military transactions of the realm.

Ricord's History of Rome.

Possesses the charm of an attractive romance. The fables with which this history abounds are introduced in such a way as not to deceive the inexperienced, while adding materially to the value of the work as a reliable index to the character and institutions, as well as the history of the Roman people.

A BRIEF HISTORY OF ANCIENT PEOPLES INTRODUCTION

A Brief History of Ancient Peoples.

With an account of their monuments, literature, and manners. 340 pages. 12mo. Profusely illustrated.

In this work the political history, which occupies nearly, if not all, the ordinary school text, is condensed to the salient and essential facts, in order to give room for a clear outline of the literature, religion, architecture, character, habits, &c., of each nation. Surely it is as important to know something about Plato as *all* about Caesar, and to learn how the ancients wrote their books as how they fought their battles.

The chapters on Manners and Customs and the Scenes in Real Life represent the people of history as men and women subject to the same wants, hopes

and fears as ourselves, and so bring the distant past near to us. The Scenes, which are intended *only for reading*, are the result of a careful study of the unequalled collections of monuments in the London and Berlin Museums, of the ruins in Rome and Pompeii, and of the latest authorities on the domestic life of ancient peoples. Though intentionally written in a semi-romantic style, they are accurate pictures of what *might* have occurred, and some of them are simple transcriptions of the details sculptured in Assyrian alabaster or painted on Egyptian walls.

THE NATIONAL SERIES OF STANDARD SCHOOL-BOOKS.

HISTORY—Continued.

The extracts made from the sacred books of the East are not specimens of their style and teachings, but only gems selected often from a mass of matter, much of which would be absurd, meaningless, and even revolting. It has not seemed best to cumber a book like this with selections conveying no moral lesson.

The numerous cross-references, the abundant dates in parenthesis, the pronunciation of the names in the Index, the choice reading references at the close of each general subject, and the novel Historical Recreations in the Appendix, will be of service to teacher and pupil alike.

Though designed primarily for a text-book, a large class of persons — general readers, who desire to know something about the progress of historic criticism and the recent discoveries made among the resurrected monuments of the East, but have no leisure to read the ponderous volumes of Brugsch, Layard, Grote, Mommsen, and Ihne — will find this volume just what they need.

From HOMER B. SPRAGUE, *Head Master Girls' High School, West Newton St., Boston, Mass.*

"I beg to recommend in strong terms the adoption of Barnes's 'History of

Ancient Peoples' as a text-book. It is about as nearly perfect as could be hoped for. The adoption would give great relish to the study of Ancient History."

HE Brief History of France.

By the author of the "Brief United States," with all the attractive features of that popular work (which see) and new ones of its own.

It is believed that the History of France has never before been presented in such brief compass, and this is effected without sacrificing one particle of interest. The book reads like a romance, and, while drawing the student by an irresistible fascination to his

task, impresses the great outlines indelibly upon the memory.

DRAWING.

BARNES'S POPULAR DRAWING SERIES.

Based upon the experience of the most successful teachers of drawing in the United States.

The Primary Course, consisting of a manual, ten cards, and three primary drawing books, A, B, and C.

Intermediate Course. Four numbers and a manual.

Advanced Course. Four numbers and a manual.

Instrumental Course. Four numbers and a manual.

The Intermediate, Advanced, and Instrumental Courses are furnished either in book or card form at the same prices. The books contain the usual blanks, with the unusual advantage of opening from the pupil, — placing the copy directly in front and above the blank, thus occupying but little desk-room. The cards are in the end more economical than the books, if used in connection with the patent blank folios that accompany this series.

The cards are arranged to be bound (or tied) in the folios and removed at pleasure. The pupil at the end of each number has a complete book, containing only his own work, while the copies are preserved and inserted in another folio ready for use in the next class.

Patent Blank Folios. No. 1. Adapted to Intermediate Course. No. 2. Adapted to Advanced and Instrumental Courses.

ADVANTAGES OF THIS SERIES.

The Plan and Arrangement. — The examples are so arranged that teachers and pupils can see, at a glance, how they are to be treated and where they are to be copied. In this system, copying and designing do not receive all the attention. The plan is broader in its aims, dealing with drawing as a branch of common-school instruction, and giving it a wide educational value.

Correct Methods. — In this system the pupil is led to rely upon himself, and not upon delusive mechanical aids, as printed guide-marks, &c.

One of the principal objects of any good course in freehand drawing is to educate the eye to estimate location, form, and size. A system which weakens the motive or removes the necessity of *thinking* is false in theory and ruinous in practice. The object should be to educate, not cram; to develop the intelligence, not teach tricks.

Artistic Effect. — The beauty of the examples is not destroyed by crowding the pages with useless and badly printed text. The Manuals contain all necessary instruction.

Stages of Development. — Many of the examples are accompanied by diagrams, showing the different stages of development.

Lithographed Examples. — The examples are printed in imitation of pencil drawing (not in hard, black lines) that the pupil's work may resemble them.

One Term's Work. — Each book contains what can be accomplished in an average term, and no more. Thus a pupil *finishes* one book before beginning another.

Quality — not Quantity. — Success in drawing depends upon the amount of *thought* exercised by the pupil, and *not* upon the large number of examples drawn.

Designing. — Elementary design is more skillfully taught in this system than by any other. In addition to the instruction given in the books, the pupil will find printed on the insides of the covers a variety of beautiful patterns.

Enlargement and Reduction. — The practice of enlarging and reducing from copies is not commenced until the pupil is well advanced in the course and therefore better able to cope with this difficult feature in drawing.

Natural Forms. — This is the only course that gives at convenient intervals easy and progressive exercises in the drawing of natural forms.

Economy. — By the patent binding described above, the copies need not be thrown aside when a book is filled out, but are preserved in perfect condition for future use. The blank books, only, will have to be purchased after the first introduction, thus effecting a saving of more than half in the usual cost of drawing-books.

Manuals for Teachers. — The Manuals accompanying this series contain practical instructions for conducting drawing in the class-room, with *definite* directions for drawing *each* of the examples in the books, instructions for designing, model and object drawing, drawing from natural forms, &c.

THE NATIONAL SERIES OF STANDARD SCHOOL-BOOKS.

DRAWING — *Continued.*

Chapman's American Drawing-Book.

The standard American text-book and authority in all branches of art. A compilation of art principles. A manual for the amateur, and basis of study for the professional artist. Adapted for schools and private instruction.

CONTENTS. — "Any one who can Learn to Write can Learn to Draw." — Primary Instruction in Drawing. — Rudiments of Drawing the Human Head. — Rudiments in Drawing the Human Figure. — Rudiments of Drawing. — The Elements of Geometry. — Perspective. — Of Studying and Sketching from Nature. — Of Painting. — Etching and Engraving. — Of Modelling. — Of Composition. — Advice to the American Art-Student.

The work is of course magnificently illustrated with all the original designs.

Chapman's Elementary Drawing-Book.

A progressive course of practical exercises, or a text-book for the training of the eye and hand. It contains the elements from the larger work, and a copy should be in the hands of every pupil; while a copy of the "American Drawing-Book," named above, should be at hand for reference by the class.

Clark's Elements of Drawing.

A complete course in this graceful art, from the first rudiments of outline to the finished sketches of landscape and scenery.

Allen's Map-Drawing and Scale.

This method introduces a new era in map-drawing, for the following reasons: 1. It is a system. This is its greatest merit. — 2. It is easily understood and taught. — 3. The eye is trained to exact measurement by the use of a scale. — 4. By no special effort of the memory, distance and comparative size are fixed in the mind. — 5. It discards useless construction of lines. — 6. It can be taught by any teacher, even though there may have been no previous practice in map-drawing. — 7. Any pupil old enough to study geography can learn by this system, in a short time, to draw accurate maps. — 8. The system is not the result of theory, but comes directly from the school-room. It has been thoroughly and successfully tested there, with all grades of pupils. — 9. It is economical, as it requires no mapping plates. It gives the pupil the ability of rapidly drawing accurate maps.

FINE ARTS.

Hamerton's Art Essays (Atlas Series):—

No. 1. The Practical Work of Painting.

With portrait of Rubens. 8vo. Paper covers.

No. 2. Modern Schools of Art.

Including American, English, and Continental Painting. 8vo. Paper covers.

Huntington's Manual of the Fine Arts.

A careful manual of instruction in the history of art, up to the present time.

Boyd's Kames' Elements of Criticism.

The best edition of the best work on art and literary criticism ever produced in English.

Benedict's Tour Through Europe.

A valuable companion for any one wishing to visit the galleries and sights of the continent of Europe, as well as a charming book of travels.

Dwight's Mythology.

A knowledge of mythology is necessary to an appreciation of ancient art.

Walker's World's Fair.

The industrial and artistic display at the Centennial Exhibition.

DR. STEELE'S ONE-TERM SERIES, IN ALL THE SCIENCES.

Steele's 14-Weeks Course in Chemistry.

Steele's 14-Weeks Course in Astronomy.

Steele's 14-Weeks Course in Physics.

Steele's 14-Weeks Course in Geology.

Steele's 14-Weeks Course in Physiology.

Steele's 14-Weeks Course in Zoölogy.

Steele's 14-Weeks Course in Botany.

Our text-books in these studies are, as a general thing, dull and uninteresting. They contain from 400 to 600 pages of dry facts and unconnected details. They abound in that which the student cannot learn, much less remember. The pupil commences the study, is confused by the fine print and coarse print, and neither knowing exactly what to learn nor what to hasten over, is crowded through the single term generally assigned to each branch, and frequently comes to the close without a definite and exact idea of a single scientific principle.

Steele's "Fourteen-Weeks Courses" contain only that which every well-informed person should know, while all that which concerns only the professional scientist is omitted. The language is clear, simple, and interesting, and the illustrations bring the subject within the range of home life and daily experience. They give such of the general principles and the prominent facts as a pupil can make familiar as household words within a single term. The type is large and open; there is no fine print to annoy; the cuts are copies of genuine experiments or natural phenomena, and are of fine execution.

In fine, by a system of condensation peculiarly his own, the author reduces each branch to the limits of a single term of study, while sacrificing nothing that is essential, and nothing that is usually retained from the study of the larger manuals in common use. Thus the student has rare opportunity to *economize his time*, or rather to employ that which he has to the best advantage.

A notable feature is the author's charming "style," fortified by an enthusiasm over his subject in which the student will not fail to partake. Believing that Natural Science is full of fascination, he has moulded it into a form that attracts the attention and kindles the enthusiasm of the pupil.

The recent editions contain the author's "Practical Questions" on a plan never before attempted in scientific text-books. These are questions as to the nature and cause of common phenomena, and are not directly answered in the text, the design being to test and promote an intelligent use of the student's knowledge of the foregoing principles.

Steele's Key to all His Works.

This work is mainly composed of answers to the Practical Questions, and solutions of the problems, in the author's celebrated "Fourteen-Weeks Courses" in the several sciences, with many hints to teachers, minor tables, &c. Should be on every teacher's desk.

Prof. J. Dorman Steele is an indefatigable student, as well as author, and his books have reached a fabulous circulation. It is safe to say of his books that they have accomplished more tangible and better results in the class-room than any other ever offered to American schools, and have been translated into more languages for foreign schools. They are even produced in raised type for the blind.

BOTANY.

Wood's Object-Lessons in Botany.

Wood's American Botanist and Florist.

Wood's New Class-Book of Botany.

The standard text-books of the United States in this department. In style they are simple, popular, and lively; in arrangement, easy and natural; in description, graphic and scientific. The Tables for Analysis are reduced to a perfect system. They include the flora of the whole United States east of the Rocky Mountains, and are well adapted to the regions west.

Wood's Descriptive Botany.

A complete flora of all plants growing east of the Mississippi River.

Wood's Illustrated Plant Record.

A simple form of blanks for recording observations in the field.

Wood's Botanical Apparatus.

A portable trunk, containing drying press, knife, trowel, microscope, and tweezers, and a copy of Wood's "Plant Record,"—the collector's complete outfit.

Willis's Flora of New Jersey.

The most useful book of reference ever published for collectors in all parts of the country. It contains also a Botanical Directory, with addresses of living American botanists.

Young's Familiar Lessons in Botany.

Combining simplicity of diction with some degree of technical and scientific knowledge, for intermediate classes. Specially adapted for the Southwest.

Wood & Steele's Botany.

See page 33.

AGRICULTURE.

Pendleton's Scientific Agriculture.

A text-book for colleges and schools; treats of the following topics: Anatomy and Physiology of Plants; Agricultural Meteorology; Soils as related to Physics; Chemistry of the Atmosphere; of Plants; of Soils; Fertilizers and Natural Manures; Animal Nutrition, &c. By E. M. Pendleton, M. D., Professor of Agriculture in the University of Georgia.

From PRESIDENT A. D. WHITE, Cornell University.

"Dear Sir: I have examined your 'Text-book of Agricultural Science,' and it seems to me excellent in view of the purpose it is intended to serve. Many of your chapters interested me especially, and all parts of the work seem to combine scientific instruction with practical information in proportions dictated by sound common sense."

From PRESIDENT ROBINSON, of Brown University.

"It is scientific in method as well as in matter, comprehensive in plan, natural and logical in order, compact and lucid in its statements, and must be useful both as a text-book in agricultural colleges, and as a hand-book for intelligent planters and farmers."

NATURAL SCIENCE—*Continued.*

PHYSIOLOGY.

Jarvis's Elements of Physiology.

Jarvis's Physiology and Laws of Health.

The only books extant which approach this subject with a proper view of the true object of teaching Physiology in schools, viz., that scholars may know how to take care of their own health. In bold contrast with the abstract *Anatomies*, which children learn as they would Greek or Latin (and forget as soon), to *discipline the mind*, are these text-books, using the sciences as a secondary consideration, and only so far as is necessary for the comprehension of the *laws of health*.

Steele's Physiology.

See page 33.

ASTRONOMY.

Willard's School Astronomy.

By means of clear and attractive illustrations, addressing the eye in many cases by analogies, careful definitions of all necessary technical terms, a careful avoidance of verbiage and unimportant matter, particular attention to analysis, and a general adoption of the simplest methods, Mrs. Willard has made the best and most attractive *elementary Astronomy* extant.

McIntyre's Astronomy and the Globes.

A complete treatise for intermediate classes. Highly approved.

Bartlett's Spherical Astronomy.

The West Point Course, for advanced classes, with applications to the current wants of Navigation, Geography, and Chronology.

Steele's Astronomy.

See page 33.

NATURAL HISTORY.

Carll's Child's Book of Natural History.

Illustrating the animal, vegetable, and mineral kingdoms, with application to the arts. For beginners. Beautifully and copiously illustrated.

Anatomical Technology. Wilder & Gage.

As applied to the domestic cat. For the use of students of medicine.

ZOÖLOGY.

Chambers's Elements of Zoölogy.

A complete and comprehensive system of Zoölogy, adapted for academic instruction, presenting a systematic view of the animal kingdom as a portion of external nature.

Steele's Zoölogy.

See page 33.

LITERATURE.

Gilman's First Steps in English Literature.

The character and plan of this exquisite little text-book may be best understood from an analysis of its contents: Introduction. Historical Period of Immature English, with Chart; Definition of Terms; Languages of Europe, with Chart; Period of Mature English, with Chart; a Chart of Bible Translations, a Bibliography or Guide to General Reading, and other aids to the student.

Cleveland's Compendiums. 3 vols. 12mo.

ENGLISH LITERATURE.

AMERICAN LITERATURE.

ENGLISH LITERATURE OF THE XIXTH CENTURY.

In these volumes are gathered the cream of the literature of the English-speaking people for the school-room and the general reader. Their reputation is national. More than 125,000 copies have been sold.

Boyd's English Classics. 6 vols. Cloth. 12mo.

MILTON'S PARADISE LOST.

THOMSON'S SEASONS.

YOUNG'S NIGHT THOUGHTS.

POLLOCK'S COURSE OF TIME.

COWPER'S TASK, TABLE TALK, &c. LORD BACON'S ESSAYS.

This series of annotated editions of great English writers in prose and poetry is designed for critical reading and parsing in schools. Prof. J. R. Boyd proves himself an editor of high capacity, and the works themselves need no encomium. As auxiliary to the study of belles-lettres, &c., these works have no equal.

Pope's Essay on Man. 16mo. Paper.

Pope's Homer's Iliad. 32mo. Roan.

The metrical translation of the great poet of antiquity, and the matchless "Essay on the Nature and State of Man," by Alexander Pope, afford superior exercise in literature and parsing.

POLITICAL ECONOMY.

Champlin's Lessons on Political Economy.

An improvement on previous treatises, being shorter, yet containing everything essential, with a view of recent questions in finance, &c., which is not elsewhere found.

ÆSTHETICS.

Huntington's Manual of the Fine Arts.

A view of the rise and progress of art in different countries, a brief account of the most eminent masters of art, and an analysis of the principles of art. It is complete in itself, or may precede to advantage the critical work of Lord Kames.

Boyd's Kames's Elements of Criticism.

The best edition of this standard work; without the study of which none may be considered proficient in the science of the perceptions. No other study can be pursued with so marked an effect upon the taste and refinement of the pupil.

ELOCUTION.

Watson's Practical Elocution.

A scientific presentment of accepted principles of elocutionary drill, with black-board diagrams and full collection of examples for class drill. Cloth. 90 pages, 12mo.

Taverner Graham's Reasonable Elocution.

Based upon the belief that true elocution is the right interpretation of thought, and guiding the student to an intelligent appreciation, instead of a merely mechanical knowledge, of its rules.

Zachos's Analytic Elocution.

All departments of elocution—such as the analysis of the voice and the sentence, phonology, rhythm, expression, gesture, &c.—are here arranged for instruction in classes, illustrated by copious examples.

SPEAKERS.

Northend's Little Orator.

Northend's Child's Speaker.

Two little works of the same grade but different selections, containing simple and attractive pieces for children under twelve years of age.

Northend's Young Declaimer.

Northend's National Orator.

Two volumes of prose, poetry, and dialogue, adapted to intermediate and grammar classes respectively.

Northend's Entertaining Dialogues.

Extracts eminently adapted to cultivate the dramatic faculties, as well as entertain.

Oakey's Dialogues and Conversations.

For school exercises and exhibitions, combining useful instruction.

James's Southern Selections, for Reading and Oratory.

Embracing exclusively Southern literature.

Swett's Common School Speaker.

Raymond's Patriotic Speaker.

A superb compilation of modern eloquence and poetry, with original dramatic exercises. Nearly every eminent modern orator is represented.

MODERN LANGUAGES.

A COMPLETE COURSE IN THE GERMAN.

By James H. Worman, A.M., Professor of Modern Languages in the Adelphi Academy, Brooklyn, L. I.

Worman's First German Book.

Worman's Second German Book.

Worman's Elementary German Grammar.

Worman's Complete German Grammar.

These volumes are designed for intermediate and advanced classes respectively.

Though following the same general method with "Otto" (that of "Gaspey"), our author differs essentially in its application. He is more practical, more systematic more accurate, and besides introduces a number of invaluable features which have never before been combined in a German grammar.

Among other things, it may be claimed for Professor Worman that he has been the first to introduce, in an American text-book for learning German, a system of analogy and comparison with other languages. Our best teachers are also enthusiastic about his methods of inculcating the art of speaking, of understanding the spoken language, of correct pronunciation; the sensible and convenient original classification of nouns (in four declensions), and of irregular verbs, also deserves much praise. We also note the use of heavy type to indicate etymological changes in the paradigms and, in the exercises, the parts which specially illustrate preceding rules.

Worman's Elementary German Reader.

Worman's Collegiate German Reader.

The finest and most judicious compilation of classical and standard German literature. These works embrace, progressively arranged, selections from the masterpieces of Goethe, Schiller, Körner, Senne, Uhland, Freiligrath, Heine, Schlegel, Holty, Lenau, Wieland, Herder, Lessing, Kant, Fichte, Schelling, Winkelmann, Humboldt, Ranke, Raumer, Menzel, Gervinus, &c., and contain complete Goethe's "Iphigenie," Schiller's "Jungfrau;" also, for instruction in modern conversational German, Benedix's "Eigensinn."

There are, besides, biographical sketches of each author contributing, notes, explanatory and philological (after the text), grammatical references to all leading grammars, as well as the editor's own, and an adequate Vocabulary.

Worman's German Echo.

Worman's German Copy-Books, 3 Numbers.

On the same plan as the most approved systems for English penmanship, with progressive copies.

CHAUTAUQUA SERIES.

First and Second Books in German.

By the natural or Pestalozzian System, for teaching the language without the help of the Learner's Vernacular. By James H. Worman, A. M.

These books belong to the new Chautauqua German Language Series, and are intended for beginners learning to speak German. The peculiar features of its method are:—

1. It teaches the language by direct appeal to illustrations of the objects referred to, and does not allow the student to guess what is said. He speaks from the first hour understandingly and accurately. Therefore,

2. Grammar is taught both analytically and synthetically throughout the course. The beginning is made with the auxiliaries of tense and mood, because their kinship with the English makes them easily intelligible; then follow the declensions of nouns, articles, and other parts of speech, always systematically arranged. It is easy to confuse the pupil by giving him one person or one case at a time. This pernicious practice is discarded. Books that beget unsystematic habits of thought are worse than worthless.

FRENCH.

Worman's First Book in French.

The first book in the companion series to the successful German Series by the same author, and intended for those wishing to *speaking* French. The peculiar features of Professor Worman's new method are:—

1. The French language is taught without the help of English.
2. It appeals to *pictorial illustrations for the names of objects.*
3. The learner speaks from the first hour *understandingly.*
4. Grammar is taught to prevent missteps in composition.
5. The laws of the language are taught *analytically* to make them the learner's own inferences (= deductions).
6. Rapidity of progress by dependence upon *association and contrasts.*
7. Strictly *graded lessons* and conversations on *familiar, interesting, and instructive topics*, providing the words and idioms of every-day life.
8. *Paradigms* to give a systematic treatment to variable inflections.
9. *Heavy type* for inflections, to make the eye a help to the mind.
10. *Hair line type* for the silent letters, and links for words to be connected, in order to teach an accurate pronunciation.

Worman's French Echo.

This is not a mass of meaningless and parrot-like phrases thrown together for a tourist's use, to bewilder him when in the presence of a Frenchman.

The "Echo de Paris" is a *strictly progressive conversational book*, beginning with simple phrases and leading by frequent repetition to a mastery of the *idioms and of the every-day language* used in business, on travel, at a hotel, in the chit-chat of society.

It presupposes an elementary knowledge of the language, such as may be acquired from the First French Book by Professor Worman, and furnishes a *running French text*, allowing the learner of course to find the meaning of the words (in the appended Vocabulary), and forcing him, by the absence of English in the text, to *think in French*.

CHER MONSIEUR WORMAN, — Vous me demandez mon opinion sur votre "Echo de Paris" et quel usage j'en fais. Je ne saurais mieux vous répondre qu'en reproduisant une lettre que j'écrivais dernièrement à un collègue qui était, me disait-il, "bien fatigué de ces insipides livres de dialogues."

"Vous ne connaissez donc pas," lui disais-je, "'l'Echo de Paris,' édité par le Professor Worman? C'est un véritable trésor, merveilleusement adapté au développement de la conversation familière et pratique, telle qu'on la veut aujourd'hui. Cet excellent livre met successivement en scène, d'une manière vive et intéressante,

toutes les circonstances possibles de la vie ordinaire. Voyez l'immense avantage il vous transporte en France; du premier mot, je m'imagine, et mes élèves avec moi, que nous sommes à Paris, dans la rue, sur une place, dans une gare, dans un salon, dans une chambre, voire même à la cuisine; je parle comme avec des Français; les élèves ne songent pas à traduire de l'anglais pour me répondre; ils pensent en français; ils sont Français pour le moment par les yeux, par l'oreille, par la pensée. Quel autre livre pourrait produire cette illusion? . . ."

Votre tout dévoué,

A. DE ROUGE-MONT.

Illustrated Language Primers.

FRENCH AND ENGLISH.

GERMAN AND ENGLISH.

SPANISH AND ENGLISH.

The names of common objects properly illustrated and arranged in easy lessons.

Pujol's Complete French Class-Book.

Offers in one volume, methodically arranged, a complete French course—usually embraced in series of from five to twelve books, including the bulky and expensive lexicon. Here are grammar, conversation, and choice literature, selected from the best French authors. Each branch is thoroughly handled; and the student, having diligently completed the course as prescribed, may consider himself, without further application, *au fait* in the most polite and elegant language of modern times.

TEACHERS' AIDS AND SCHOOL REQUISITES.

CHARTS AND MAPS.

Baade's Reading Case.

This remarkable piece of school-room furniture is a receptacle containing a number of primary cards. By an arrangement of slides on the front, one sentence at a time is shown to the class. Twenty-eight thousand transpositions may be made, affording a variety of progressive exercises which no other piece of apparatus offers. One of its best features is, that it is so exceedingly simple as not to get out of order, while it may be operated with one finger.

Clark's Grammatical Chart.

Exhibits the whole science of language in one comprehensive diagram.

Davies's Mathematical Chart.

Elementary mathematics clearly taught to a full class at a glance.

De Rupert's Philological and Historical Chart.

This very comprehensive chart shows the birth, development, and progress of the literatures of the world; their importance, their influence on each other, and the century in which such influence was experienced; with a list for each country of standard authors and their best works. Illustrating also the division of languages into classes, families, and groups. Giving date of settlement, discovery, or conquest of all countries, with their government, religion, area, population, and the percentage of enrolment for 1872, in the primary schools of Europe and America.

Eastman's Chirographic Chart. Family Record.

Giffins's Number Chart.

Teaches addition, subtraction, multiplication, and division. Size, 23 x 31 inches.

Marcy's Eureka Tablet.

A new system for the alphabet, by which it may be taught without fail in nine lessons.

McKenzie's Elocutionary Chart.

Monteith's Pictorial Chart of Geography.

A crayon picture illustrating all the divisions of the earth's surface commonly taught in geography.

WM. L. DICKINSON, *Superintendent of Schools, Jersey City, says.*

"It is an admirable amplification of the system of pictorial illustration adopted

in all good geographies. I think the chart would be a great help in any primary department."

Monteith's Reference Maps. School and Grand Series.

Names all laid down in small type so that to the pupil at a short distance they are outline maps, while they serve as *their own key* to the teacher.

Page's Normal Chart.

The whole science of elementary sounds tabulated.

Scofield's School Tablets.

On five cards, exhibiting ten surfaces. These tablets teach orthography, reading, object-lessons, color, form, &c.

Watson's Phonetic Tablets.

Four cards and eight surfaces; teaching pronunciation and elocution phonetically. For class exercises.

Whitcomb's Historical Chart.

A student's topical historical chart, from the creation to the present time, including results of the latest chronological research. Arranged with spaces for summary, that pupils may prepare and review their own chart in connection with any text-book.

Willard's Chronographers.

Historical. Four numbers: Ancient chronographer, English chronographer, American chronographer, temple of time (general). Dates and events represented to the eye.

APPARATUS.

Bock's Physiological Apparatus.

A collection of twenty-seven anatomical models.

Harrington's Fractional Blocks.

Harrington's Geometrical Blocks.

These patent blocks are *hinged*, so that each form can be disassembled.

Kendall's Lunar Telluric Globe.

Moon, globe, and tellurian combined.

Steele's Chemical Apparatus.

Steele's Geological Cabinet.

Steele's Philosophical Apparatus.

Wood's Botanical Apparatus.

RECORDS.

Cole's Self-Reporting Class Book.

For saving the teacher's labor in averaging. At each opening are a full set of tables showing any scholar's standing at a glance, and entirely obviating the necessity of computation.

Tracy's School Record. {Desk edition.
{Pocket edition.

For keeping a simple but exact record of attendance, deportment, and scholarship. The larger edition contains also a calendar, an extensive list of topics for compositions and colloquies, themes for short lectures, suggestions to young teachers, &c.

Benet's Individual Records.

Brooks's Teacher's Register.

Presents at one view a record of attendance, recitations, and deportment for the whole term.

Carter's Record and Roll-Book.

This is the most complete and convenient record offered to the public. Besides the usual spaces for general scholarship, deportment, attendance, &c., for each name and day, there is a space in red lines enclosing six minor spaces in blue for recording recitations.

National School Diary.

A little book of blank forms for weekly report of the standing of each scholar, from teacher to parent. A great convenience.

REWARDS.

National School Currency.

A little box containing certificates in the form of money. The most entertaining and stimulating system of school rewards. The scholar is paid for his merits and fined for his short-comings. Of course the most faithful are the most successful in business. In this way the use and value of money and the method of keeping accounts are also taught. One box of currency will supply a school of fifty pupils.
